1.0 Introduction

Rodgers Leask Environmental Ltd (RLE) has been commissioned by St Modwen Developments Ltd (St Modwen) to update and further develop a Controlled Waters Detailed Quantitative Risk Assessment (CWDQRA) of the potential risk to Controlled Waters for the Glan Llyn development at Llanwern, Newport (herein referred to as the site). The previous version of this CWDQRA was prepared by Atkins Limited (Atkins), the latest version of which was identified as: Document Reference: 5111373-LLA-OUT-0257, Version: 3 and dated February 2017. It is recommended that reference be made to the aforementioned Atkins Report, in order to obtain greater detail on the known/documented Reporting background to this site.

The principal objectives of the current exercise is to provide, as practicably possible, future surface water flow contributions from the site are compliant upon entry in to the Monks' Ditch, surface water course, which bisects the site, following the redevelopment of the Glan Llyn site for mixed residential and commercial redevelopment and further limiting the amount of material which require off-site removal by virtue of its contaminative potential towards local Controlled Waters.

These introductory comments provide a narrative and rationale for the assumptions made within this updated model, and also provide considerations relating to the temporary management of the water whilst redevelopment is being undertaken, and sustainability of the brownfield project.

As alluded above, an interim state will exist where the site has been reclaimed, but full residential and commercial development is under construction. The reclamation, in terms of surface water quality, will be at its most effective when it is fully developed. The underlying natural clay currently provides a barrier to downward migration of water and the reens (surface water ditches) which are cut into the natural clay and/or peat, drain the water within the Made Ground.

1.1. Atkins Controlled Waters Detailed Quantitative Risk Assessment of 2016

The initial DQCWRA prepared by Atkins (Version: 3 and dated February 2017), was issued with the intention that, as site specific information was collected, the assessment would be reviewed and updated. It was described as the starting point and that the criteria were understood to be conservative. The CWDQRA modelled two site conditions for the mixed use development comprising; residential and commercial end usage.

The residential end use was assumed to have a rainwater interception/ infiltration ratio of 60:40. The commercial end use was assumed to have a rainwater interception/ infiltration ratio of 95:5. The interception is where roofs, roads and hard paving take the rain water and transfer it directly into the surface water reens. The infiltration is where rainwater lands

on grassed or landscaped areas and is able to percolate into the construction material (soils, piling mat, sub base etc) and underlying post-development Made Ground. The current evapotranspiration rate for grassed areas is estimated as 600mm/a against an annual rainfall rate of 953mm/a. The earlier Atkins value utilised, (applicable to permeable areas) was; 416mm/annually.

The Atkins CWDQRA, that generated the initial criteria, assumed that 100% of the infiltrated rainwater (12.85mm per year or 1.3% of total rainfall) mm/a) percolated through the construction material and in to the Made Ground.

Upon derivation of their soil re-use criteria (calculated to be expressed as mg/kg for direct comparison against actual soil analytical data obtained), it was previously noted by Atkins in their 2017 CWDQRA Report and demonstrated in their associated Table 5.5, that the maximum and average soil sample concentrations exhibit some exceedances for inorganic compounds, copper and vanadium. It was also noted that there were exceedances in surface water analyses for iron, manganese, cyanide, and ammoniacal nitrogen. Although these had not been previously analysed by Atkins in soil samples, subsequent analyses has included these determinands.

Exceedances were also noted in soil samples analysed for organic compounds, especially C_{12}-C_{35} species aromatic TPH (total petroleum hydrocarbons), and a number of PAH (polynuclear aromatic hydrocarbon) species as compared to the derived soil re-use criteria. Concentrations of PAHs present in actual soil analytical data obtained were, in some cases, over one order of magnitude in excess of the calculated re-use criteria, suggesting that attenuation, particularly of heavy fraction TPH and PAHs is likely to be an issue on this site requiring further consideration as part of the proposed remedial and redevelopment works. Although previous analyses of soil samples undertaken by Atkins did not include phenols, recent analyses has included this determined.

1.2. Rationale for Updated Model

The principal rationales for reviewing the model that generated the initial criteria have been:

1. The amount of additional field, site specific, data collected since preparation of the earlier Atkins CWDQRA;

2. The remedial benefits of the currently proposed pre-development turnover and reengineering process were not included in the earlier Atkins CWDQRA. Further details of this proposed Made Ground re-engineering strategy to be employed are provided by Rodgers Leask Environmental Ltd in their Reclamation Performance Specification A – Turnover – Technical Note, dated 14/12/18, Ref: 17480-RLE-18-XX-RP-O-1016). A copy of this Technical Note is provided in **Appendix A** to the current Report.

The large and increasing amount of site specific field data for soils and surface waters has provided further confirmation that the criteria, which is based on theoretical values, is conservative. This is indicated where chemical results for soil placed do not appear to deliver the modelled concentrations to the surface water. The undeveloped site is currently at a worst case scenario where rainfall is free to percolate through material that has not been reengineered. Reengineering and redevelopment will only reduce infiltration and mobilisation serving to improve the currently monitored conditions.

In 2016, geotechnical information relating to the permeability of the Made Ground was assessed (Atkins Ltd Permeability Infiltration Technical Note Ref: 5111373-LLA-OUT-0256, dated 15th December 2016), but this was not used in the model for the Atkins 2017 CWDQRA. A copy of this Technical Note is provided in **Appendix B** of the current Report. The Atkins Ltd Technical Note presented information on the characteristics of the reengineered ground. The earthworks specification for the placement of material (following the turnover to natural clay), requires particle size distribution (PSD) tests, density tests, compaction tests and air void tests on each layer to validate the material has been compacted sufficiently. The particle size distribution within the Made Ground is known to be well graded and when compacted, the permeability is assessed as having a low permeability/poor drainage potential. A number of falling head tests were undertaken within a reengineered plot, which returned failed test results. The reengineering therefore has a remediation/stabilising benefit, by creating a low permeability material and this can be validated by the geotechnical information already collected.

ln contrast to the reengineered ground, the construction materials (6F2 piling mat & clean soils) placed above the Made Ground are likely to be of good drainage potential (if they are not, then they will only serve to further limit the downward migration of rainwater).

The low permeability reengineered material inhibits the downward migration of infiltrated rainwater as the pore water in the construction material does not readily flow into the material with much reduced pore spaces (air voids <10%). Lowering the permeability of this material also greatly increases time taken by the perched water to travel within the material.

The engineered characteristics have two distinct remedial benefits as follows:

1. The volume of infiltrated water entering the body of reengineered Made Ground is reduced, therefore the volume of water exposed to mobile contaminants is also reduced;
2. The time taken for migration of the perched water within the reengineered ground is greatly increased and therefore, the volume of perched water reaching the surface water via this route is reduced, increasing the ratio of clean rainwater in the surface water reens. Where this passage is also through areas of cleaner reengineered Made Ground, there are likely to be benefits associated with increased contamination attenuation prior to reen discharge. These are the areas of the site where some retardation (degradation and/or sorption) of contaminants within the Made Ground is

considered possible. On this basis it is proposed to place 'cleaner' Made Ground closer to the reens which are known to be the surface water receptors for the perched waters.

The Atkins CWDQRA, that generated the initial criteria, assumed that in areas of soft landscaping, 100% of the infiltrated rainwater (12.85mm per year or 1.3% of total rainfall) percolated through the construction material (imported top soils) and in to the Made Ground. This value takes account of estimated surface-water run-off (55% of total rainfall) and evapotranspiration (43.7% of total rainfall). It is considered likely that the lowest achievable, permeability of the post-development Made Ground is like to be in the region of ($1x10^{-7}$ m/s).

It was also apparent in the Atkins CWDQRA and Conceptual Site Model that although lateral drainage within the capping layer was anticipated, this wasn't accounted for in the calculations, where it assumed that essentially all (1.3% of the total rainwater) passed into the underlying post-development Made Ground. It is therefore reasonable to assume that a reduction in infiltration into post-development Made Ground will be enabled by the placement of higher permeability ground surface construction materials (imported soils) and any possible introduced gradient within this layer which will encourage an element of lateral flow.

In order to gauge potential impacts on the existing calculated soil reuse criteria, a process of sensitivity analyses was therefore proposed using possible scenarios where 40% of the 12.85mm per year (5.14mm/year) or 5% (0.64mm/year) penetrates into the underlying post-development Made Ground. It is recognised that this modelling is of a further potential reduction in what is already, apparently, a low rate of rainwater infiltration (1.3% of total rainfall). Reuse criteria would then be derived for the range of determinands previously selected by Atkins, and it was proposed that these criteria now also include iron, manganese, cyanide, ammoniacal nitrogen and phenol, which would be modelled in current revision to the Report.

It was considered that the very low 5% (0.64mm/year) infiltration rate may not necessarily be achievable, but was introduced as a mechanism to reflect distance from the surface water receptors (existing reens), and effectively represent a greater travel of infiltrated water. It was proposed that the findings should be superseded by modelled travel time parameters, when appropriate, and from this would be derived what would be considered to be realistic achievable soil reuse criteria.

1.3 Natural Attenuation from Site Features

It is also considered that there is a potential for natural attenuation benefits from further improving and expanding the existing surface water features on the site, which mainly comprise reens and ponds/small lakes. This is anticipated particularly through:

1. Further establishing the vegetation within the reens which will help reduce the concentrations of organic contaminants and particularly nutrients such as ammoniacal

nitrogen. The reens are known to vegetate rapidly and require regular maintenance to remove surplus growth;

2. Undertaking organic matter enrichment of soils along margins of the reens and ponds/lakes into which water penetrating the Made Ground are likely to discharge. This could be undertaken by placement of locally excavated peat (obtained from Alluvial and underlying Tidal Flat Deposits) and other soils containing high concentrations of organic matter. This should enable a further stripping out of low concentrations of PAHs and TPH within these discharge waters. Amendment of these soils with other materials will also be considered, taking into consideration further knowledge of the residual contaminant profile, in order to provide a passive sustainable solution to the long-term remediation of this site.

2.0 Site History and Environmental Setting

2.1 Site Setting

The Glan Llyn development site is located south of Llanwern, immediately east of Newport at National Grid Reference (NGR) ST 36101 86848. The site covers an area of approximately 243 ha which comprises previously developed land (Section 2.2). The site is bound to the north by a railway line and to the south by Queen's Way (A4810). The operational Tata steelworks is located adjacent to the eastern boundary and a north-south drainage ditch borders the western boundary, beyond which lies Newport Retail Park. A plan showing the site's location is presented on Drawing 18669-RLE-19-XX-DR-O-0004. The site is proposed to be redeveloped as a mixed residential and commercial development (Drawing8111-008-A0111). Residential development is proposed for the majority of the site, whilst commercial development is limited to the Celtic Business Park area in the east of the site (Drawing 8111-008-A0111).). A copy of this Drawing is provided to the rear of this Report.

2.2 Site History

Details of the documented site history are provided in the above-noted Atkins CWDQRA Report dated February 2017. However, in summary, the site was extensively developed as a steelworks by Richard Thomas and Baldwins Ltd in the 1960s. Prior to construction, marshland and arable farmland within the site boundary was subject to significant land raise and engineering to bring ground level to current levels. Within the confines of the development site, steelworks ancillaries included but were not limited to; mineral stockyards, blast furnaces, offices, railway sidings, a 'Bit Mac' plant and coking works. Steel making operations ceased in the western half of the steelworks site in 2001, with the majority of infrastructure demolished in 2004, following land transfer to St. Modwen Developments Ltd.

It is much of the material used as part of this pre-development land raise, together with demolished former steelworks buildings and structures that comprise the existing Made Ground across the site, which will be subject to the proposed reengineering and compaction works associated with this redevelopment.

Approximately 20% of the development has been completed up to August 2019, including near completion of two residential phases (Phase 1 & Phase 2), the construction of two commercial units (Amazon & CAF), the park and a pub within the Western Sub Area.

2.3 Geology

2.3.1. Published Geology

The BGS GeoIndex (BGS, 2016a) indicates that Superficial Tidal Flat Deposits comprising clays and silts underlie the areas of interest. The BGS Lexicon of Named Rock Units (BGS, 2016b)

describes these deposits as: *'normally a consolidated soft silty clay, with layers of sand, gravel and peat. Characteristically low relief; from the tidal zone'* Bedrock geology underlying the areas of interest comprises mudstones of the Mercia Mudstone Group (BGS, 2016a); the BGS Lexicon of Named Rock Units (BGS, 2016b) describes the Mercia Mudstone as: *'dominantly red, less commonly green-grey, mudstones and subordinate siltstones with thick halite-bearing units in some basinal areas. Thin beds of gypsum/anhydrite* [are] *widespread, sandstones are also present.'* Given the history of development within the areas of interest, it is anticipated that a layer of Made Ground will be present across the proposed developments.

2.3.2. Local Geology

The Glan Llyn development site benefits from several phases of GI and the ground model for the site is well constrained. For ease of discussion and brevity, a summary of local geology underlying the site is presented in Atkins Table 2-1 below (reproduced from their February 2017 Report). However, a full discussion of local geology within each development phase is presented in the respective "Ground Investigation and Ground Conditions" section of the geo environmental reports (Atkins; 2015b, 2015c, 2015d). Boreholes drilled as part of the 2016 CWRA Ground Investigation (IFA, 2016) confirm the presence of Made Ground, Tidal Flat Deposits and Bedrock across the site, as outlined in Table2-1 below.

Table 2-1 Summary of Local Geology (Atkins, 2015 a)

Geological Unit		Indicative Geological Composition	Approximate Thickness
Topsoil		Soft brown slightly sandy clay.	Nominal thickness, only locally
Made Ground	Made Ground 1	Grey occasionally clayey, sandy gravel of and angular to sub-angular fine to coarse slag with occasional tarmac, concrete, brick, limestone and ceramic / fused slag.	0.02 2.6 m
	Made Ground 2	Red brown / brown clayey sandy gravel (locally gravelly sand) with cobbles and boulders	
	Made Ground 3	Red brown / brown soft to firm sandy gravelly clay with cobbles and boulders. Gravel includes sub-rounded to angular fine to coarse burnt shale, brick, slag, sandstone, mudstone, shale and occasional coal.	
Tidal Flat Deposits	Upper Tidal Clay	Generally very soft to firm blue grey slightly gravelly silty clay with rare localised pockets of peat.	7 – 10 m (IFA, 2016)
	Upper Peat	Generally a spongy dark brown occasionally clayey pseudo-fibrous to fibrous peat.	
	Lower Peat	Generally a spongy to plastic dark brown occasionally clayey occasionally sandy pseudo-fibrous to amorphous peat.	
	Lower Tidal Clay	Generally described as a soft to firm bluish grey slightly sandy slightly gravelly clay gravel is of angular to sub-angular fine to medium sandstone.	
	Red Clay	Generally described as a firm to stiff red brown mottled grey slight gravelly clay, gravel is angular to sub-angular fine to coarse mudstone.	
	Basal Sand	Generally a medium dense light brown slightly silty slightly gravelly fine grained sand the gravel is of sub-rounded to sub-angular fine siltstone and quartzite.	
Bedrock	Mercia Mudstone Group	Weathered Mercia Mudstone being described as stiff to very stiff reddish brown slightly gravelly clay and extremely weak to weak occasionally laminated red brown mudstone.	Encountered, thickness not proven

2.3.3 Post-development Ground Conditions

The post-development ground conditions on site are as detailed in Table 2-2 below. Existing Made Ground is to be excavated and re-compacted to comply with the Atkins geotechnical specification for the development (Atkins, 2016b). In addition, it was proposed that a 1 in 100 gradient (0.01) be applied to the surface of the Made Ground to prevent ponding and promote lateral drainage within the construction materials.

Potential further mitigation to promote lateral flow that may be considered is the provision of a drainage blanket to cap the reengineered material and increasing the fall from the centre of a plot to periphery.

Table 2-2 Post-Development Ground Conditions

Unit	Approximate Thickness	Description
Impermeable Construction Materials/ Housing Sub-base/Permeable Topsoil	0.6 m	Imported clean topsoil/construction materials
Piling Mat*	0.5 m	Imported 6F2 (*may be included within 600mm of construction materials)
Made Ground	1.5 – 2.0 m	Excavated and re-compacted Made Ground
Tidal Flat Deposits	7.0 – 10.0 m	No change from current conditions
Bedrock (Mercia Mudstone Group)	>1,350m	No change from current conditions

2.4 Hydrogeology

The following details are based upon information presented in the Atkins 2017 Report, and reviewed again prior to preparation of the current update.

2.4.1. Published Hydrogeology

Groundwater maps previously available on the Environment Agency website (Atkins, 2015a) show that the Mercia Mudstone bedrock deposits below the proposed developments are classified as a Secondary B Aquifer. The Environment Agency define a Secondary B Aquifer as being: *'predominantly lower permeability layers which may store and yield limited amounts of groundwater due to localised features such as fissures, thin permeable horizons and weathering. These are generally the water-bearing parts of the former non-aquifers.'*

The Tidal Flat Deposits are classified as non-productive strata which are defined by the Environment Agency as being: *'deposits with low permeability that have negligible significance for water supply or river base flow'.*

It is understood from investigations carried out by Atkins that the Environment Agency website indicated that there were no groundwater abstractions within 1 km of the proposed developments. Information presented on the GroundSure Enviro Data Viewer website (http://groundsure.io/), accessed August 2019, indicates that the Site is not located within a Groundwater Source Protection Zone (SPZ).

2.4.2. Local Hydrogeology

A site-wide programme of monthly groundwater level monitoring was undertaken from May to November 2016 in the shallow and deep wells installed during the CWRA GI (Drawing 5111373-LLA-DWG-EG-0295) to inform the hydrogeological conceptual site model. A copy of this Drawing is provided in the Appendices to the current Report.

This monthly monitoring was subsequently continued until 2017.

A summary of groundwater levels recorded in the deep and shallow wells were presented in Appendix A of the Atkins 2017 CWDQRA Report and are reproduced in the current Report (**Appendix C**). It is indicated that groundwater level monitoring and water strike data recorded during the Ground Investigations (GI) of each site development phase, were presented in the "Ground Investigation and Ground Conditions" section of the relevant geo-environmental Report (Atkins; 2015b, 2015c, 2015d); and are summarised in the CWRA Position Statement (Atkins, 2015a).

It was considered that groundwater levels recorded during the CWRA GI and subsequent monitoring suggested that the groundwater is present beneath the proposed development as follows (Atkins, 2015a):

- Shallow / perched groundwater within the Made Ground (shallow boreholes); and
- Groundwater within the Tidal Flat Deposits (confined to the basal sand layers) and Mercia Mudstone (deep boreholes).

Groundwater monitored within the deep boreholes was considered to be primarily derived from the bedrock geology, and hydraulic continuity between the upper perched shallow groundwater and 'regional' groundwater was considered likely to be limited. Post-development, the excavation and re-compaction of the Made Ground was recognised as likely to reduce its permeability, lowering still further, the hydraulic continuity.

The permeability of the reengineered material based on the compaction necessary to attain the requirements of the specification is likely to consistently achieve low permeability or poor drainage characteristics. This is likely to be a permeability of 10^{-7} m/s.

Downward percolation of water through the Tidal Flat Deposits was considered to be limited due to the low permeability of the clay-rich strata. This is likely to cause water to accumulate within the overlying Made Ground. Regional groundwater within the Basal Sands of the Tidal Flat Deposits and Mercia Mudstone bedrock is confined by the overlying clay within the Tidal Flat Deposits and is under sub-artesian pressure (Atkins, 2015a). These conditions are further confirmed by the presence of water strikes consistent with the top of the Mudstone/Basal Sands which rose several metres within a short time period (IFA, 2016).

Where the piezometric level in the regional aquifer is higher than shallow perched water then the shallow perched water system is likely to be hydraulically contained with limited downward leakage permitted. However, it is unknown how groundwater conditions will change throughout the hydraulic year within the post-development site. As outlined by Atkins (2015a), during hydraulic conditions where the piezometric level is below the level of the shallow perched water, slow downward migration of this water through the Tidal Flat

Deposits is to be expected. Table 2-4 of the Atkins 2017 CWDQRA Report, below (reproduced from their February 2017 Report), presents deep – shallow groundwater levels (mAOD) for the available groundwater level data across the site. It was indicated by Atkins that based on a review of the water levels in the deep and shallow borehole pairs, there are examples of both conditions being present at the proposed development site during all 2016 monitoring rounds. It was indicated that the majority of differences between piezometric levels are less than half a metre across the site, with only four occurrences where shallow piezometric levels are at or greater than 1.00m than deep levels (BH05 03/11/16, BH06 03/11/16, BH21 05/10/16 and 07/07/16, BH30 05/10/16).

*n/a indicates no two corresponding samples available for comparison (i.e. dry borehole/no data), where value is negative deep groundwater levels are lower than shallow, positive values indicate deep groundwater levels above shallow.

Further analysis of regional groundwater data (13/10/2015) from the boreholes installed into the bedrock geology was undertaken in the CWRA Position Statement (Atkins, 2015a). Deep groundwater contours produced suggest a regional groundwater flow direction towards the south and south east towards the estuary of the River Severn, which is broadly expected. This is confirmed by analysis of recent groundwater level monitoring data.

Review of the shallow perched water system indicates that it is likely to be extremely complex with no discernible single flow direction (Atkins, 2015a). The Made Ground is known to be highly heterogeneous (Table 2-1), resultant flow of perched water is likely to be discontinuous and tortuous through permeable and connected pathways only. In addition, flow within the Made Ground is fragmented across the site by the extensive network of surface water drainage ditches (reens) across the site (Section 2.5.1); it is anticipated that flow converges towards these surface water features where permeable pathways exist within the Made Ground. As a result of natural clay lining of the reens around the periphery of the site (Section 2.5.1), no lateral hydraulic connection exists between the Made Ground onsite and surrounding superficial deposits.

2.4.2.1. Hydrogeological Properties

Capping Drainage Layer

The gravels of the capping drainage layer are expected to have a permeability of approximately 1x10-3 m/s (Freeze and Cherry, 1979), assuming the material to have good drainage characteristics consistent with a clean gravel/sand (Atkins, 2016b).

Made Ground

It was indicated by Atkins, that soakaway tests undertaken within the re-engineered Made Ground onsite (in accordance with BRE 365 (BRE, 2007)) produced very little seepage and therefore analysis of results was not possible. It was noted that composition of the Made Ground as indicated by Particle Size Distribution (PSD) laboratory tests approximate the hydraulic conductivity of the post-development Made Ground at 1x10-7 m/s (Atkins, 2016b). It was therefore indicated that the assigned hydraulic conductivity of the re-engineered Made Ground be based on the values included within Barnes (2010) for a material with poor drainage characteristics as indicated by the soakaway tests. It was noted that this value is consistent with previous analysis undertaken by Atkins. The results of these tests are presented in Table 2-5, as reproduced below.

Table 2.5: Properties of the Re-engineered Made Ground

Made Ground	PSD No./ Average	BRE Soakaway Test Result	Adopted Permeability(*k*)
Test 1	102 No./ 11% fines, 22% sand, 62% gravel, 5% cobbles	Fell 4mm in 3hrs	1 x 10^{-7} m/s
Test 2		Fell 20mm in 2hrs	1 x 10^{-7} m/s

2.5. Hydrology

2.5.1. Surface Water Features

It was previously indicated by Atkins that, the surface water drainage onsite comprises several man-made surface water drainage ditches (reens) cut into the natural clay which divide the site north to south, receiving water from the land to the north in addition to onsite drainage and baseflow. A maximum channel flow of 10.64 l/s was previously recorded at sampling location D5N. The reens are connected to east-west drains which run the length of the site along the A4810 (Queen's Way Road) within 50 m from the southern boundary and the northern carrier drain within the site adjacent to the northern boundary(Drawing 5111373-LLA-DWG-EG-0408); ultimately discharging to the water treatment works at the operational Tata steelworks to the east. Drawing 5111373-LLA-DWG-EG-0408 depicts the current surface water drainage onsite and indicates sampling locations.

Monks' Ditch, a main river (Waterbody ID GB109056026850) crosses the site flowing north to south. The river flows across the site in a fully contained deep piled concrete channel approximately 7 m wide and 3 m deep (Rodgers Leask, 2016) before crossing the Gwent Levels to the south as a natural channel (Section 2.5.3) and discharging to the Severn Estuary via a tidal exclusion gate. A number of reens and watercourses controlled and maintained by Cyfoeth Naturiol Cymru / Natural Resources Wales (CNC/NRW) surround the site and are described in the surface water drainage strategy (Rodgers Leask, 2016).

A comprehensive surface water drainage strategy for the site has been developed by Rodgers Leask (2016), considering areas already developed (Western Sub Area and parts of the Celtic Business Park) and those yet to be developed. The strategy outlines the sustainable surface water management planned for the finished development. Approximately 399,000 m3 of storage is planned within the site, taking the form of an extensive network of blueways/reens, lakes and Sustainable Drainage Systems (SuDS), receiving all surface water runoff from the site. A post-development surface water drainage plan is presented in Drawing D12- 084-512 and summarised below:

- Blueways (Reen 1, Reen 2, Julian's Reen, Ellen Reen, East Lake Reen, King's Wall Reen and Celtic Business Park Reens) – primary surface water channels comprising existing and newly created reens which will be engineered to flow south to north across the site, culminating in a west-east channel adjacent to the northern boundary of the site, from which water will be discharged to Monk's Ditch. Reens within the site boundary will be unlined (other than being cut into the underlying clay to achieve the required invert level therefore the base and deeper parts of banks will be formed in the natural clay);
- Greenways – high level dry, shallow ditches intended to channel overland surface water from the development plots into the blueways;
- Lakes – a number of lakes and ponds are anticipated to be connected to the blueway system to provide amenity with some additional storage for surface water runoff; and
- Monks' Ditch – surface water from the site is proposed to be pumped to the Main River at a maximum flow rate of 750 l/s as specified by CNC/NRW.

The strategy as submitted (Rodgers Leask, 2016), states that discharges to Monks' Ditch will be allowed once the specified quality criteria and quality control systems have been

established and are met, until that point discharges to the Tata system will continue from the development site.

2.5.2. Rainfall

In the absence of an onsite rain gauge, rainfall data used within the Atkins 2017 CWDQRA assessment was taken from MAFF (1976) for the area surrounding Newport. Literature values for annual total rainfall, (953 mm, MAFF, 1976) are comparable to available data from nearby CNC/NRW rain gauge at Newport for the year 2015 (945 mm).

2.5.3. Designated Areas

Gwent Levels (Nash and Gold Cliff) Site of Special Scientific Interest (SSSI) encompasses the area between the southern site boundary and the Severn Estuary and comprises a large area of ancient grazing marshes, farmed wetland, and reens. The area is part of a series of adjoining SSSI designated for their wildlife and archaeology; specifically water beetles and dragonflies found in the reens, farmland birds, and brown hare, otter and water vole.

3.0 Conceptual Site Model

3.1 Introduction

A Conceptual Site Model (CSM) was previously prepared by Atkins for the Glan Llyn site, as a whole, and presented in their 2017 CWDQRA Report. It was indicated that the CSM, which was considered to be representative of the site in an un-remediated, undeveloped scenario, considered all available geological and hydrogeological information relating to the proposed development to produce a CSM upon which a detailed assessment of the risk to Controlled Waters could be assessed. Risks to Human health via inhalation, direct ingestion or dermal contact of soils did not form part of the CSM. Again, it is recommended that the relevant chapter of the Atkins Report is read in conjunction with this section of the current Report. However, much of the earlier Atkins CSM is presented again below for convenience.

3.2 Potential Sources of Contamination

The following potential sources of contamination were identified with respect to Controlled Waters considering the available historical and recent data for the site:

The Made Ground, which was historically used to build up the level of the site was known to include imported waste products (slag, concrete, brick, burnt shale) from other steelworks in addition to natural deposits (Table 2-1).

Chemical compounds which have the potential to contaminate the ground outlined by the Department of Environment (DoE, 1995) as being associated with metal production industry are: metals and metalloids, inorganic compounds, acids and alkalis. Contaminants, particularly related to coke-making include; PAHs, cyanides, ammoniacal liquors, sulphur and sulphates, BTEX VOCs and also include petroleum-based fuels and oils. Contaminants of Concern (CoC) are presented in Section 5.1.1.

It was noted by Atkins that groundwater within the bedrock has previously been impacted by contaminants associated with the former steel producing industry formerly located on this site. However given the direction of the groundwater flow and the location of elevated concentrations a link between the steelworks as a source and regional groundwater could not be confirmed.

3.3 Potential Receptors

Receptors relating to Controlled Waters are identified to comprise:

- Monks' Ditch (into which surface water from the development site is pumped);
- Engineered surface water reens onsite;
- Perched groundwater within the Made Ground;
- Groundwater within the Tidal Flat Deposits Unproductive Strata; and
- Mercia Mudstone Secondary B Aquifer.

It was indicated that the Made Ground and Tidal Flat Deposits (unproductive strata) are not considered to be a Controlled Waters receptor in the context of the assessment due to their anticipated low resource potential. The post-development surface water reens within the site were not considered to be Controlled Waters given the artificial nature of their origin and the fact that discharge from this system will always be entirely managed by on site pumping stations. The reens are therefore treated as part of the engineered water management system in the same way that SuDS features are on many developments.

Monks' Ditch, as a Main River, was considered to the principal receptor for any Controlled Waters impact at the site.

3.4 Potential Pathways

Potential Controlled Waters pathways were identified as follows:

Leaching of soil-borne contamination in Made Ground and subsequent lateral migration through permeable pathways in Made Ground to Monks' Ditch via onsite reens.

No effective pathway was identified between the shallow groundwater in the Made Ground and the deep groundwater within the Mercia Mudstone Secondary B Aquifer, due to the low permeability of the clay-rich Tidal Flat Deposits.

3.5 Potential Pollutant Linkages

It was assessed that contamination present within the Made Ground onsite is anticipated to directly leach into the underlying perched shallow groundwater via infiltration and diffusion. The degree of leaching from the source materials present within the Made Ground is a function of portioning to the soil matrix and volatilisation potential to the gaseous phase. Little dilution was anticipated to occur within the Made Ground as the site was considered to be hydraulically isolated from the surrounding superficial deposits by reens formed in the natural clay, preventing inflow of uncontaminated groundwater. The base of the reens are also known to be excavated into the clay-rich Tidal Flat Deposits.

The prevailing flow of perched groundwater was anticipated to be separated along the central north-south divide of each sub-area, flowing laterally to the adjacent reen following the slope of the Made Ground (Section 2.3.3). Groundwater flow was considered to be able to move laterally within the Made Ground without impedance. However, it is recognised that areas of low hydraulic conductivity are likely to exist in the Made Ground (i.e. due to the presence of silts and clays), which will baffle flow locally and prevent bulk advection of contaminants.

It was assumed that no dilution occurs within the shallow groundwater in the Made Ground and that concentrations of contaminants reach equilibrium. Substantial dilution will occur within the reens as groundwater mixes with surface water runoff from the site.

Water in the reens is proposed to be physically pumped into the Controlled Waters receptor, Monks' Ditch; details of which are outlined in the Surface Water Drainage Strategy (Rodgers

Leask, 2016). Currently it is understood that the surface water discharge from site flows into the Tata surface water system and is controlled and discharged as part of their industrial discharge consent.

As previously outlined, due to the low resource potential and low permeability nature of the Made Ground, Tidal Flat Deposits and Mercia Mudstone, in addition to the restricted pathway between shallow and deep groundwater, no credible groundwater receptors were realised. A diagrammatic CSM was prepared, which has been reproduced by RLE (dated 05/07/19) and is provided in **Appendix D**.

4.0 Contamination Data Assessment

4.1. Water Quality Standards

The Atkins CSM identified Monks' Ditch as a Controlled Waters receptor for the site. Therefore, the annual average Inland Surface Waters EQS applicable under the Water Framework Directive was adopted as the primary WQS (DEFRA/Welsh Ministers, 2015). Where a value was not available for a particular element or compound, then the following standards were used in order of preference:

- EU Statutory EQS (Protection of Surface Water Quality) (Council Directive 2000/60/EC);
- UK Statutory EQS (Protection of Aquatic Life) (Council Directive 76/464/EEC);
- UK Non-statutory EQSs (Protection of Aquatic Life) (Council Directive 76/464/EEC) and;
- UK Drinking Water Standard (DWS) (Water Supply (Water Quality) Regulations, 2000).

There are no current UK WQS for TPH; however, a concentration of 0.01 mg/l was used, which is based on the UK DWS in the former 1989 regulations (Water Supply (Water Quality) Regulations, 1989).

It is considered upon further review that the EQS Values for Controlled Water as applied in the earlier Atkins 2017 CWDQRA, still remain appropriate for this site, and therefore have remained unchanged in the current Revision.

4.2 Soil Quality Assessment Methodology

In order to determine the potential impacts through leachability of the existing insitu Made Ground, derivation of Screening Values (expressed as mg/kg) was previously undertaken by Atkins for a range of determinands using the Environment Agency calculation provided in their Remedial Target Worksheet (Level 1 Soils), using, where possible, site specific data. These previously derived Screening Values have been retained and utilised as part of the current revised assessment. Details as to the methodology utilised are provided in the earlier Atkins 2017 CWDQRA Report, and it is recommended that this methodology employed be read in conjunction with the current Report.

4.3 Atkins Earlier Findings from July 2015 to September 2016

For greater detail of these findings, reference should be made here to the earlier Atkins 2017 CWDQRA Report. However, in brief summary:

4.3.1 Soils

From analyses of 243 (No.) samples of Made Ground recovered from unremediated stockpiles across the site, it was noted, upon comparison, that total concentrations of determinands (which included metals, petroleum hydrocarbons and PAHs), were found in many of these samples, to exceed their respective calculated Level 1 Soils Screening Values,

based upon application of the proposed site specific EQS Values for Controlled Waters. The full results are presented in Appendix B of the earlier Atkins 2017 CWDQRA Report.

4.3.2 Soil Leachates

114 (No.) soil leachates were also generated from samples of Made Ground recovered. It was noted that upon analyses for an appropriate suite of inorganic determinands (mainly metals), and upon comparison with the proposed site specific EQS values, that a number of these (particularly chromium, copper and vanadium), were also found in many of these samples to exceed the respective EQS values. The full results are presented in Appendix B of the earlier Atkins 2017 CWDQRA Report.

4.3.3 Groundwater Samples

Concentrations of a range of metal determinands, consistent with the former usage of the site in the metal production industry, were also analysed in shallow and deep groundwater samples recovered from boreholes installed across the site. The full results are presented in Appendix C of the earlier Atkins 2017 CWSQRA Report. In view of the relative degree of hydraulic isolation of the shallow and deep groundwater horizons present across the site, these findings were considered separately.

4.3.3.1 Shallow Groundwater Horizon Samples

These samples were considered to be representative of groundwater in contact with existing Made Ground present on the site.

A total of 68 (No.) samples were recovered from the shallow groundwater within the Made Ground across 24 locations during May, June and July 2016 based upon a specification presented in an earlier monitoring strategy (Atkins, 2016a). The WQS standards adopted for groundwater quality screening are as outlined in Section 4.1 of the Atkins 2017 CWDQRA Report, and a summary of exceedances is presented in Table 4-3 of the same Report as it was determined that the LoD (limit of detection) was greater than or equal to the WQS for many of the determinands, for screening purposes exceedances were only considered for samples where analytical results were found to be above the LoD.

It was noted that, as expected, the determinands in exceedance of the WQS in the soil samples (consistent with those associated with the metal production industry (DOE, 1995)) are also reflected in the results of analyses of the shallow groundwater samples.

A review and discussion of the results of analyses of shallow groundwater samples is presented below, together with consideration of the results of more recent (post 2017) monitoring and analyses.

4.3.3.2 Deep Groundwater Horizon Samples

A total of 138 (No.) samples were recovered from the deep groundwater within the Tidal Flat Deposits and underlying Mudstone across 47 locations during May, June and July 2016 based upon a specification presented in an earlier monitoring strategy (Atkins, 2016a). Again, as the LoD was greater than or equal to the WQS for many of the determinands, for screening purposes exceedances were only considered for samples above the LoD. A summary of WQS exceedances is presented in Table 4-4 of the Atkins 2017 CWDQRA Report.

4.3.4 Surface Water Quality

It was indicated that surface water quality data was collected monthly from the reens and ponds onsite based upon a specification presented in an earlier monitoring strategy (Atkins, 2016a). A total of 104 (no.) samples were collected from June to November 2016 and were screened as outlined in Section 4.1 of the Atkins 2017 CWDQRA Report. Again, as the LoD was greater than or equal to the WQS for many of the determinands, for screening purposes exceedances were only considered for samples above the LoD.

4.3.4.1 Onsite Surface Water Quality

Of the 104 (No.) samples, 94 (No.) were from onsite. The determinands detected above the WQS within the onsite surface water samples were considered to be broadly consistent with those identified within the soil samples (Table 4-1 of the Atkins 2017 CWDQRA Report). Cyanide, iron, manganese, SVOC and VOCs were in exceedance of the WQS in the surface water, however they were not tested for in the soil samples, so a comparison may not be made.

Upon further review of the results obtained, it may be noted that:

67% exceeded the ammoniacal nitrogen WQS;
6% exceeded the total cyanide WQS;
4.3% samples exceeded the copper WQS, where bioavailable copper is considered only;
5.4% exceeded the vanadium WQS;
6.5% exceeded the nickel WQS.

4.3.4.2. Monks' Ditch Surface Water Quality

Of the 104 (No.) samples recovered, 10 (No.) were from the Monks' Ditch monitoring locations (MD-N and MD-S). The exceedances of the WQS present within Monks' Ditch were presented in Table 4-6 of the Atkins 2017 CWDQRA Report. It was indicated that the exceedances reported were spread across all samples and collection dates. As the Monks' Ditch is understood to be hydraulically isolated as it flows through the Glan Llyn Llanwern Site, then assuming that this is the case, then it may be inferred that where elevated concentrations of contaminant determinands are recorded, then these are likely to have originated from an offsite up-gradient/up-flow source.

4.4 Assessment of Data from 2017 Onwards

4.4.1 Soils

Subsequent soils analyses have been undertaken on samples recovered from across the site, over a period from 01/05/17 to 03/04/19, with a total number of 1806 (No.) samples being analysed. The results of analyses are provided in **Appendix E** of the current Report Details of specific areas of the site where these samples have been recovered are presented in **Appendix F** of the current Report. From analyses of 1806 (No.) samples of Made Ground recovered from unremediated ground across the site, it may be noted again, upon comparison, that total concentrations of determinands (which included metals, petroleum hydrocarbons and PAHs), may be found in many of these samples, to exceed their respective calculated Level 1 Soils Screening Values, based upon application of the proposed site specific WQS Values for Controlled Waters.

4.4.2 Soil Leachates

Subsequent soil leachate analyses have been undertaken on samples recovered from across the site, over a period from 01/06/18 to 11/04/19, with a total number of 1121 (No.) samples being analysed for metals. The results of analyses are provided in **Appendix G** of the current Report. Details of specific areas of the site where these samples have been recovered are presented in **Appendix F.** It was noted that upon comparison of metals results with the proposed site specific WQS values, that a number of these, again, particularly; arsenic, chromium, copper, vanadium and to a lesser extent; lead and zinc, were also found in a significant number of these samples to exceed their respective WQS values. It should be recognised, however, that the laboratory preparation of leachate samples produces results which will tend to be conservative and of limited relevance where shallow surface water quality results are available (as in the case of this site), for comparison purposes.

However, it is noted that of the samples analysed:

- 83% exceeded the arsenic WQS;
- 54% exceeded the chromium WQS;
- 86% exceeded the copper WQS;
- 66% exceeded the nickel WQS;
- 76% exceeded the selenium WQS;
- 92% exceeded the vanadium WQS;
- 42% exceeded the lead WQS;
- 66% exceeded the zinc WQS;
- A low to very low number of exceedances for BTEX VOCs were recorded;
- No samples exceeded the respective WQS values for PAHs;
- No samples exceeded the respective WQS values for TPHs.

4.4.3 Groundwater

No additional groundwater monitoring samples have been recovered.

4.4.4 Surface Water Quality

4.4.4.1 Onsite Surface Water Quality

A further significant volume of additional data has been obtained from monitoring of the quality of surface waters across the site, with a total number of 998 samples being recovered over a period from 06/03/2018 to 30/04/19. The results of analyses are provided in **Appendix H** of the current Report. It is noted that of the samples analysed:

- 63% exceeded the ammoniacal nitrogen WQS;
- 3.4% exceed the free cyanide WQS;
- No samples exceeded the copper WQS where bioavailable copper is considered only;
- 25.5% exceeded the vanadium WQS
- No samples exceeded the nickel WQS where bioavailable nickel is considered only;
- 4.3% of samples exceeded the TPH WQS;
- 90% of samples exceeded their WQS for a range of PAHs.

4.4.4.2 Monks' Ditch Surface Water Quality

Of the 104 (No.) samples taken, 48 (No.) were from the Monks' Ditch monitoring locations (MD-N and MD-S). The flow direction is from MD-N to MD-S, in a southerly direction.

It may be noted that for the MD-N location:

- 16% exceeded the ammoniacal nitrogen WQS;
- 4% exceeded the aliphatic TPH (C_{21}-C_{35} aliphatic carbon chain) WQS;
- 88% of samples exceeded their WQS for a range of PAHs;
- Exceedances were noted for a range of metals in unfiltered samples, but did not exceed their respective WQS in filtered samples and corrected for bioavailability;
- pH values recorded ranged between 7.80 and 8.24 and were within the proposed WQS range.

It may be noted that for the MD-S location:

- 39% exceeded the ammoniacal nitrogen WQS;
- 83% of samples exceeded their WQS for a range of PAHs;
- Exceedances were noted for a range of metals in unfiltered samples, but did not exceed their respective WQS in filtered samples and corrected for bioavailability;
- 22% of samples exceeded the proposed WQS range for pH. Values recorded ranged between 7.54 and 9.68.

4.5. Discussion of Results

4.5.1 Surface Waters

4.5.1.1 Inorganics

Compared to earlier data, there appears to be a significant increase in the number of surface water samples analysed which exceed the vanadium WQS concentration. It is known that

vanadium becomes concentrated (between 2-3% mass) in BOF- (basic oxygen furnace slag). This is considered likely to be the vanadium source (particularly vanadium dicalcium silicate phases), with vanadium leaching out into surface waters, as the slag weathers. Vanadium concentrations were noted to be particularly elevated in surface water samples recovered from position R4C, and to extent in R1C. Vanadium concentrations appear to become more diluted/attenuated as surface water drains towards Surface Water Pumping Station No. 2. However it appears that the vanadium precipitates out, as pH values tend to lower (become more neutral) and some incorporation with iron oxyhydroxides (particularly goethite) which are another slag weathering by-product takes place.

There appears to be no obvious increase or decrease in recorded concentrations of metal determinands within upstream reens and positions downstream within the Kings Wall Reen. However, cyanide concentrations appear to increase downstream within the reen system, possibly as leached contributions are made from deposited wastes associated with the former coking works located within the northern central section of the site. However, there is evidence for decrease again in cyanide concentrations, further downstream, potentially due to complexation with metals such as iron and nickel, particularly in the higher pH conditions which are likely to prevail. There is also noted to be evidence of a possible contribution here from ammoniacal liquors associated with the former coking works.

When iron concentrations are compared, it may be noted that in post 2017 samples analysed, only 0.5% of the samples exceeded WQS values for filtered samples whilst 22% exceeded the WQS in unfiltered samples. This suggests that iron is flocculating/precipitating out as the leached solution becomes more oxygenated. Within the reens, this iron precipitation as an oxi-hydroxide is likely to take place contemporaneously with the dissolved vanadium.

When compared with earlier results obtained by Atkins prior to 2017, the number of WQS exceedance for concentrations of ammoniacal nitrogen remain largely unchanged (63% exceeding WQS) in post-2017 data, although some concentration values were found to be more elevated in recently obtained surface water samples.

The number of WQS exceedances for cyanide in post-2017 data appear comparable to those obtained by Atkins pre-2017.

4.5.1.2 Organics

Although there are a slightly higher proportion of surface water samples recovered from across the site, more generally, that exceed the WQS for PAH concentration (over 90.58% exceed the WQS for fluoranthene), it is also noted that for water samples recovered from the Monks' Ditch, which is understood to be hydraulically isolated from the Glan Llyn Llanwern site, PAH (again; fluoranthene) exceedance of the WQS in up to 88.0% of the samples (Monks' Ditch North MD-N) and 82.6% of samples (Monks' Ditch South MD-S) was noted. The source of these slightly elevated PAH concentrations determined in the Monks' Ditch is unclear, although again, it suggests the presence of an upstream off-site contributing source.

There appears to be no discernible reduction in PAH concentrations generally when comparing the earlier and post-2017 surface water analytical results.

TPH concentrations were exceeded in 4.3% of surface water samples recovered from across the site. These findings are considered to be consistent with TPH impact from isolated hotspots within the Made Ground.

4.5.2 Groundwaters

4.5.2.1 Inorganics

The following discussion is largely taken from the Atkins 2017 CWDQRA Report and updated, as considered appropriate. Consistent with soil leachate samples, elevations of pH are greatest in the shallow groundwater, with an average of 9.6, and 49% of samples greater than the WQS range of 6-9. In comparison pH values in the deep groundwater are lower; the reported average is 8, and less than 9% of samples are in exceedance. The elevated pH in shallow groundwater samples as compared to deep groundwater samples is likely to be attributable to impacts from weathering of BOF slag, whilst the pH of deeper groundwater samples can be influenced by oxidation of sulphidic minerals which will lower the pH of groundwater in contact with these minerals. However, in this case where an average pH of 8 is reported, the findings would suggest an absence of evidence for impact from weathering BOF slag or significant impact from sulphide oxidation.

Copper, lead, nickel and selenium are present at higher concentrations and produce more exceedances of the WQS within the shallow groundwater. Concentrations of vanadium are also found to be much greater in shallow groundwater; the maximum shallow groundwater value is 485 mg/l (WQS exceedance in 28% of samples) in comparison to the deep groundwater maximum of 157 mg/l (WQS exceedance in 7% of samples). Again, the elevated vanadium concentrations are likely to be attributable to weathering of the BOF slag, which may also be impacting on concentrations of copper, lead, nickel and selenium in shallow groundwater, as compared to the deeper groundwater samples recovered where slag weathering by-products are less likely to impact.

Concentrations of ammoniacal nitrogen are reduced by half in the shallow groundwater in comparison to the deep. Atkins (2015a) suggested that the lower ammoniacal nitrogen concentrations present in the shallow groundwater are the result of upward leakage and that the direction of the groundwater flow from the north west indicates that the elevated concentrations of ammoniacal nitrogen are more likely to be from an off-site diffuse source, such as from infiltrated runoff from agricultural activities.

Maximum and average concentrations of dissolved arsenic are considerably higher in the deep groundwater (220 µg/l and 32.1 µg/l respectively) than in the shallow (40.5 µg/l and 9.2 µg/l respectively). Similarly for total arsenic, 13% of the deep samples but only 3% of shallow samples are in exceedance of the WQS (50 µg/l). Concentrations of iron, cadmium, chromium, manganese are also elevated within the deep groundwater in comparison to the

shallow. The lower concentrations of these metals determined in surface water samples as compared to deeper samples may be due in part to greater dilution of the surface groundwaters, as the results of soil leachate analyses suggests that Made Ground across the site are likely to contain significant leachable concentrations of these metals.

4.5.2.2 Organics

The majority of TPH samples in both shallow and deep groundwater are reported below the LoD, however a few boreholes are proven to be hot spots for TPH contamination. Maximum concentrations of TPH are up to two orders of magnitude greater in shallow groundwater in comparison to deep groundwater. In shallow groundwater, TPH in exceedance of the WQS are limited to less than 15% of the total sample population for each exceeding contaminant. The samples reported in exceedance during the May 2016 sampling round are distributed across nine locations, however samples in the June and July rounds exceeding for three or more contaminants are limited to locations CWWS-04, CWWS-19 and CWWS-11.

In deep groundwater, TPH in exceedance of the WQS are limited to less than 5% of the total sample population for each exceeding contaminant with the exception of aromatic >EC21-EC35 (16.7%). Sample locations with exceedances of two or more TPH in a single sample are locations CBBH04, CBBH05, CWCP- 04, CWCP-19 and CWCP-11.

PAHs are present in both the shallow and deep groundwater; concentrations of contaminants and frequency of exceedances are greater in the shallow groundwater. As for TPH, maximum concentrations within the shallow groundwater are up to two orders of magnitude larger than in the deep. Exceedances are widespread within the shallow groundwater, with a percentage of samples exceeding up to 69%; within deep groundwater exceedances are limited to 14%, with the exception of fluoranthene (29%) and benzo(a)pyrene (28%).

Exceedances of SVOCs and VOCs above the LoD are limited, and remain below 9% of the shallow groundwater and 2.2% of the deep groundwater total sample population for each contaminant.

A wide range of contaminants are found to exceed the WQS in both the shallow and deep groundwater. However, the chemical signatures of each aquifer unit are distinct and the greatest concentrations and percentages of exceedances are not simply attributed to the shallow groundwater. It is possible that due to the fluctuating upwards and downwards gradients across the site as presented in Section 2.4.2 (Table 2-4) groundwater from either unit may be influencing the other. For example, where deep groundwater levels are lower than shallow, downward migration of water into the Tidal Flat Deposits is possible. Atkins (2015a) calculated that the un-retarded breakthrough of shallow groundwater through the Tidal Flat Deposits is likely to be 9 years. Taking into account conservative partition coefficients for naphthalene (a mobile PAH) and cadmium, the retarded breakthrough of naphthalene and cadmium is likely to be 644 and 1,435 years, respectively. Considering this,

it is unlikely that the contamination identified within the deep groundwater originated within the made ground.

5.0 Detailed Quantitative Risk Assessment and Re-use Assessment

5.1. Overview

It was indicated in the earlier Atkins 2017 CWDQRA Report, that the purpose of this assessment was to define, for a set of potential contaminants, the maximum concentration in the soil that does not pose a risk to the Controlled Waters receptor (re-use criteria). Where site soil concentrations, for one or more contaminants are greater than the re-use criteria, then in the absence of soil remediation or water treatment prior to discharge, a risk to Controlled Waters may exist.

5.1.1. Contaminants of Concern

Based on the site contamination status and known contaminants associated with steelworks (DoE, 1995), calculation of re-use criteria are to be undertaken for the Contaminants of Concern (CoCs) outlined in below. The current contamination status of the site is outlined above in Section 4; the assessment highlighted several metals, TPH and PAH that exceed the appropriate criteria. This essentially remains unchanged for the updated assessment.

Table 5-1: Contaminents of Concern (COCs)

Compound Type	Compounds
Heavy Metals/Metalloids	Arsenic, cadmium, chromium, copper, iron, lead, vanadium, manganese, mercury, nickel, selenium, zinc.
Other Inorganics	Ammoniacal nitrogen, cyanide.
Organics	Ethylbenzene, xylene, PCB, phenol.
TPH Bands	TPH aliphatic >C5-C6, TPH aliphatic >C6-C8, TPH aliphatic >C8-C10, TPH aliphatic >C10-C12, TPH aliphatic >C12-C16, TPH aliphatic >C16-C21, TPH aliphatic >C21-C35, TPH aliphatic >C35-C44, TPH aromatic >C5-C7 (Benzene), TPH aromatic >C7-C8 (Toluene), TPH aromatic >C8-C10, TPH aromatic >C10-C12, TPH aromatic >C12-C16, TPH aromatic >C16-C21, TPH aromatic >C21-C35, TPH aromatic >C35-C44, TPH Aromatic >C40-C44.
PAHs	Acenaphthene, acenaphthylene, anthracene, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(g,h,i)perylene, chrysene, di-benz(a,h)anthracene, indeno(1,2,3-cd)pyrene, fluoranthene, fluorene, naphthalene, phenanthrene, pyrene.

5.1.2. Compliance Point

In order to be protective of the Controlled Waters receptor outlined in Section 4.5, determination of the site specific compliance point has been undertaken in general accordance with the RTM (Environment Agency, 2006). The compliance point has been assigned to the point of discharge into the receptor (Monks' Ditch). Consistent with the contamination data assessment (Section 4), the WQS (Water Quality Standards) have been

set at the EQS in order to be protective of the principal Controlled Waters receptor (Section 4.1).

5.2. Dilution Assessment

5.2.1. Rationale

It was previously indicated that in order to maintain discharge of EQS compliant waters into the Controlled Waters receptor (Monks' Ditch), concentrations within the reens must be retained at or below the EQS. Due to the anthropogenic controls on discharges of water from the on-site reens to Monks' Ditch, in order to calculate the maximum concentration allowable for each contaminant within the excavated and re-compacted Made Ground (re-use criteria) the average annual water balance for the entire site is applied. This is considered appropriate given that EQS values are in relation to the annual average concentration.

Shallow groundwater is known to originate from infiltrating precipitation only, as the Made Ground of the site is hydraulically contained (Section 2.4.2). The remainder of the precipitation is either lost to evapotranspiration/evaporation or constitutes surface water runoff, and is diverted directly to the onsite drainage reens by SuDS (Section 2.5.1). Therefore, contaminant concentrations present in the shallow groundwater within the Made Ground are subject to dilution within the reens by clean SuDS drainage. As outlined in Section 2.3.3, the proportion of proposed impermeable to permeable surface area differs between the residential area and the Celtic Business Park commercial area. Resultantly, individual re-use criteria values were previously produced for each contaminant (Table 5-4 of Atkins 2017 CWDQRA Report), within each development area due to the differing volumes of water available for dilution.

As indicated in the current Introduction, the earlier CWDQRA prepared by Atkins (Version: 3 and dated February 2017), was issued with the intention that, as further site specific information was collected, the assessment would be reviewed and updated. It was described as the starting point and that the re-use criteria generated were understood to be conservative. An assumption was also made that 100% of the infiltrated rainwater percolated through the construction material and in to the Made Ground.

Since preparation of the Atkins 2017 CWDQRA Report, further consideration has been given (Rodgers Leask Environmental Ltd - Reclamation Performance Specification A – Turnover – Technical Note, dated 14/12/18, Ref: 17480-RLE-18-XX-RP-O-1016), to the pre-construction reclamation methodology to be employed across the site. The particle size distribution of the Made Ground is known to be well graded, and when compacted, the permeability is assessed as having poor drainage potential, with when appropriately placed, expected values in the region of 10^{-7}m/s.

Consideration has also been given to the application of differing standards of compaction of the Made Ground, and as a result, alteration of the rates of incident water infiltration. In order to consider the impacts of reducing infiltration rates into the Made Ground (impacts of which are likely to be greatest in areas of the site proposed for residential reusage where greater areas of soft landscaping will be present), two modelling scenarios have been considered in comparison with the Atkins previously assumed 100% infiltration into the underlying Made Ground. These models assume a greater proportion of incident rainwater

being directed laterally within the clean surface soils and 6F2 granular blanket, towards the reens. On this basis, the assumption is made that these redirected waters remain uncontaminated and provide further dilution of the waters passing through the Made Ground and ultimately discharging into the reens. In order to provide values which are likely to be 'typical' and 'potentially achievable', the following scenarios (details of which are outlined in Section 1.2 above), have been considered:

1. A 40% infiltration rate into underlying Made Ground which should be easily achievable;
2. A 5% infiltration rate into underlying Made Ground which, it is considered may be potentially achievable.

5.2.2. Methodology

The methodology employed in the current updated CWDQRA is that utilised previously by Atkins in their 2017 CWDQRA. The maximum (annual average) contaminant concentration possible within the perched groundwater in the Made Ground is calculated using dilution within the reens onsite as per Equations 3 to 7 below, whilst retaining concentrations at the EQS. Again, no allowance has been made for dilution of discharged water within Monks' Ditch as part of this calculation, as this being the receptor, it is proposed that the WSQ in this Controlled Water be maintained (as far as possible) at EQS values.

A summary of the methodology is provided below:

$$EQS = (Cgw + Qgw)/Qr \quad \text{Equation 3}$$

$$Cgw = (EQS \times Qr)/Qgw \quad \text{Equation 4}$$

- Where:
  - EQS (mg/l) = Environmental Quality Standard
  - C_{gw} (mg/l) = annual average groundwater contaminant concentration
  - Q_{gw} (m^3/a) = groundwater flow
  - Q_r (m^3/a) = reen flow

$$Qr = Qgw + Qol + (RO \times permeable\ surface\ area) \quad \text{Equation 5}$$

$$Qgw = (R - ET - RO) \times permeable\ surface\ area \quad \text{Equation 6}$$

$$Qol = (R - E) \times impermeable\ surface\ area \quad \text{Equation 7}$$

- Where:
  - R (mm/a) = total annual rainfall
  - E (mm/a) = evaporation
  - RO (mm/a) = runoff

The calculated annual average groundwater contaminant concentration Cgw (mg/l) values have been converted to Made Ground solid Cmg (mg/kg) values using Equation 8.

$$Cmg = Cgw \times ((Kd + (\theta w + \theta a \times H))/Pc) \quad \text{Equation 8}$$

- Where:
  - C_{mg} (mg/kg) = annual average Made Ground (solid) concentration
  - Kd (l/kg) = contaminant partition coefficient
  - Θw (-) = water filled porosity
  - Θa (-) = air filled porosity
  - H (-) = Henry's law constant
  - Pc (g/cm^3) = soil bulk density

5.2.3. Parameterisation

A summary of key input parameters is presented in Table 5-2 and Table 5-3 below. The full chemical input parameters and justifications are included in **Appendix I** of the current Report.

Table 5-2: Physical Parameters

Parameter	Unit	Value	Comment/Justification/Source
Average Annual Rainfall	mm/a	953	MAFF, 1976
Evapotranspiration	mm/a	416	MAFF, 1976. Applicable to permeable areas
Evaporation	%	10	Grimmond & Oke, 1999. Evaporation from impermeable surface area as a percentage of total rainfall.
Runoff coefficient	%	55	National Coal Board, 1982 (See Figure E-1)
Residential Permeable Area	m^2	676,000	Rodgers Leask, 2016
Residential Impermeable Area	m^2	1,014,000	Rodgers Leask, 2016
Commercial Permeable Area	m^2	45,000	Rodgers Leask, 2016
Commercial Impermeable Area	m^2	405,000	Rodgers Leask, 2016

Table 5-3 Chemical Parameters

Parameter	Abbreviation	Unit	Value	Comment/Justification/Source
Fraction of Organic Carbon	foc	fraction	0.024	Site specific value - average foc from 243 samples of Made Ground
Air Filled Porosity	θa	fraction	0.0037	Site specific value – average θa from 3 samples of Made Ground
Water Filled Porosity	θw	fraction	0.5	Site specific value – average θw from 3 samples of Made Ground
Dry Bulk Density	Pc	g/cm^3	1.36	Site specific value – average Pc from 3 samples of Made Ground

5.2.4. Assumptions and Limitations

The following assumptions and limitations are inherent within the modelling undertaken:

- Dilution calculations produce maximum likely average concentrations of contaminants (re-use criteria) within the Made Ground;
- Dilution methodology does not account for any dilution within Monks' Ditch at the point of discharge;
- Incident infiltrating rainwater is considered to flow laterally through the capping drainage layer, with varying proportions entering the underlying Made Ground. A 5% infiltration and a 40% infiltration rate into the underlying Made Ground have been modelled;
- No infiltration is assumed to occur within the impermeable area;
- Limited retardation (degradation and/or sorption) of contaminants within the Made Ground is considered given the extensive area of potential source materials across the site:
- Dilution calculations assume simultaneous discharge of the annual volume of surface water runoff and infiltrated water, providing a worst case volume of potentially contaminated shallow groundwater;

- No allowance has been made for additional dilution as a result of inflows to the reen system from the land to the north, as it is understood that these flows are minimal;
- The site geology and hydrogeology are assumed to be homogeneous, and parameter values and contaminant concentrations used are based on site-specific data, where available;
- Where no site-specific data are available, literature sources have been used to develop suitable parameters considered likely to reflect site conditions;
- Made Ground geology by its very nature is likely to be both laterally and vertically variable following finalisation of site development;
- Data presented by third parties has been incorporated into this report. These data have been assumed to be correct for the purposes of this assessment; and
- This assessment has been made considerate of the proposed post-development ground conditions and cover. Should this change, then the site may require re-assessment.
- It should be noted that the assessment undertaken herein and re-use criteria is for protection of Controlled Waters only. The re-use criteria derived are not necessarily protective of risk to Human Health. Re-used materials must also be geotechnically suitable, however this has not been considered as part of this assessment.

5.2.5. Material Re-use Criteria

The calculated maximum concentration of each PCOC (Re-use Criteria) in Made Ground (mg/kg) based upon the two scenarios of a 40% infiltration rate into underlying Made Ground and a 5% infiltration rate into underlying Made Ground are presented in Table 5.4 (**Appendix J**) of the current Report.

The updated results have been formatted to allow direct comparison with the earlier derived Atkins re-use criteria where 100% infiltration rate into underlying Made Ground has been assumed.

The calculated re-use criteria specified are intended to be protective of the Controlled Waters receptor with regard to the post-development site, and will, compared to earlier derived values, facilitate the greater re-use of existing on-site Made Ground in general accordance with a Remediation Strategy (Section 6.2). As previously indicated, it should be noted that re-use criteria do not apply where there is evidence of contamination in soil or Made Ground in excess of solubility (i.e. free phase product)

5.3 Contaminant Attenuation Assessment

It may be noted from Table 5.4 **(Appendix J**) that assuming only a 5% infiltration of incident rainwater into reengineered Made Ground, there remain exceedances of the respective re-use criteria in both residential and commercial redevelopment scenarios, for manganese (within a residential area reusage only) but particularly for a number of PAH species within both commercial and residential reusage areas.

Given that it is proposed within the reengineered Made Ground, to achieve a permeability of approximately $1x10^{-7}$ m/s, then it is considered that, particularly where organic CoC are considered (such as PAHs), that there is a potential for consideration of attenuation through processes of degradation/biodegradation of these leached species within the Made Ground

in view of their likely significant residence time prior to discharge into a local surface water reen.

However, given that the extent of these residual contaminant sources are likely to be of widespread (albeit variable contribution) presence within the reengineered Made Ground, then the potential for attenuation of these contaminants within the Made Ground between their source and the designated receptor (surface water reen) will be compromised. This needs to be appreciated within the further assessment undertaken, as outlined below:

5.3.1 EA Remedial Target Worksheet (Level 3 Groundwater) Assessment

In order to further consider the potential for attenuation of the residual contaminants within the Made Ground, this has been undertaken using the Environment Agency calculations provided in their Remedial Target Worksheet (Level 3 Groundwater) using, where possible, site specific data, as indicated below:

Table 5.3.1: Site Specific Data Sources Utilised in RT Worksheet Level 3 Groundwater Assessment

Variable	Value Utilised	Data Source
Width of aquifer at source	500m	Site measurements and likely width of each separate redevelopment perpendicular to directed perched groundwater flow towards appropriate reen.
Plume thickness at source	2.0m	Based upon proposed thickness of reengineered Made Ground and assumption that full thickness of Made Ground represents potential contaminant source
Saturated aquifer thickness	1.5m	Based upon typical likely groundwater levels in reengineered Made Ground.
Bulk Density of aquifer materials	1.36g/cm^3	Site specific test data
Effective Porosity of aquifer	0.08	Site specific test data
Hydraulic Gradient	0.0133	Estimation - also based upon earlier estimation used by Atkins
Hydraulic Conductivity of aquifer	8.64E-03m/d (1.0E-7m/s)	Based upon proposed permeability to be achieved following turning and reengineering of Made Ground
Distance to Compliance Point	20m	Assumed to be typical distance to surface water reen. However further dilution of contaminants will take place in reens from uncontaminated runoff from redevelopment

Using site-derived soil analyses concentration data for a range of determinands taken from 2017 onwards, maximum derived concentrations (mg/kg) in each case were then utilised for the modelled determinands. These data were then input into the equation presented in the EA Table 5.2 – soil-water partitioning of the EA Remedial Targets Methodology Guidance (2006) and a pore-water concentration Cp was determined. Soil/water partition coefficient (Kd) values utilised were site specific, and derived from those generated by Atkins (Table E4 of the Llanwern Controlled Waters Detailed Quantitative Risk Assessment Version 3.0 (February 2017)).

Consideration has also been given as to the application in the Level 3 Groundwater Remedial Target Calculation of applying 'degradation of organics in all phases' or whether a 'dissolved

pollutants only' variable should be applied. It is considered that there are likely to be different degradation rates for dissolved phase and free product. Evidence for choosing an 'all phases' variable was based upon:

- Site observations made on 09/05/19, where it was noted that hydrocarbon free-product was also present on water surface within some of the recent excavations, albeit mainly as surface iridescence, (together with probable dissolved phase). Therefore, there was considered to be evidence for the presence in site soils of hydrocarbons in both dissolved (laboratory evidence) and free-phase (site observations).

- Given in this instance that the scenario being considered is near surface degradation and biodegradation, then oxidation and volatilisation are likely to be fairly important means of loss of both free-product and dissolved phase, and will probably encourage a faster rate of degradation than would be likely at greater depth within a more anaerobic/less oxygenated environment. However, it has been noted that 'applying degradation rate to dissolved pollutants only' appears to add more conservativity to the model, so it has been proposed to utilise this variable.

The calculated pore-water value was then considered to be representative of the initial contaminant concentration in groundwater at the plume core, and utilised in the Level 3 Groundwater Remedial Target Calculation, as provided in the Excel Worksheets accompanying the current CWDQRA Report revision Draft.

The selected determinands chosen for modelling were from within (but not all) of those where soil concentrations were found from chemical analyses carried out to continue to exceed the calculated 5% and 40% infiltration scenarios reuse criteria. These determinands included metals: iron, manganese and vanadium and PAHs, benzo(a)pyrene, benzo(b)fluoranthene and naphthalene.

In the case of the Remedial Target modelling carried out to date, no specific consideration of 5% and 40% infiltration scenarios has taken place, and the assessment was carried out essentially to gauge the potential extent of attenuation of these specific determinands within the ground where these soils may be placed, with receiving surface waters being assumed to be existing reens, which have been taken as the Compliance Points. For initial calculation purposes, it has been assumed that compliant material proposed to be reused, would be placed no nearer than 20m from these reens.

It is proposed that the calculations may be revisited and updated, should it be considered appropriate, as more detailed information becomes available on the proposed site redevelopment layout.

Calculated values for Contaminants of Concern (CoC), as derived using the Level 3 Groundwater Excel Worksheets, are provided in **Appendix K** to the current Report. Where determined maximum soil concentrations exceed the calculated 40% and 5% infiltration reusage criteria, the initial contaminant porewater concentration in groundwater is

calculated based upon the maximum soil concentration recorded for each determinand, utilising the Equation provided in Table 5.2 of the EA Remedial Targets Methodology Guidance. In order to consider the impact of different concentrations of the above determinands, these scenarios have also been modelled using average porewater concentrations (calculated from average soil concentrations) utilising the Equation provided in Table 5.2 of the EA Remedial Targets Methodology Guidance. Copies of the associated Excel spreadsheets modelled for these same determinands and based upon average porewater concentrations are also provided in **Appendix K**.

As indicated above, in selecting the specific determinands for modelling, Level 3 Groundwater calculations have been carried out for a representative range of PAHs and metals, as actual concentrations of these have been found from analyses of site soils to exceed the calculated 40% and 5% infiltration reusage criteria, rather than only considering contaminants currently determined in the reens which are found to exceed the proposed EQS Values. The reasoning for this is based upon the rationale that existing water quality within the reens may not necessarily be representative of the water quality following excavation and replacement of this Made Ground prior to redevelopment. However existing surface water quality has been considered when assessing which determinands to model, and it was not considered appropriate to model ammoniacal nitrogen attenuation, as in a number of cases, exceedances were noted for this determinand in incoming off-site surface waters (as indicated above). It also appeared that cyanide concentrations deplete during flow through the reens, potentially due to complexation with metals such as iron and nickel, particularly in the higher pH conditions which are likely to prevail initially.

For this exercise, the modelling has therefore included the following determinands, with iron, manganese and vanadium being considered representative of metal behaviour and benzo(a)pyrene, benzo(b)fluoranthene and naphthalene of PAHs :

- Benzo(a)pyrene –
- Benzo(b)fluoranthene
- Naphthalene
- Iron
- Manganese
- Vanadium

Discussion of Findings

PAHs

As indicated above, the PAHs modelled have included benzo(a)pyrene, benzo(b)fluoranthene and naphthalene.

Although naphthalene concentrations in some site soils were found to be elevated in concentration, this PAH is readily attenuated, probably mostly through processes of volatilisation and aerobic biodegradation as indicated in the Level 3 Groundwater Excel Worksheets, (**Appendix K)** to the current Report.

It may be noted that the PAHs determined in surface water and shallow groundwater samples recovered, which were found to be most significantly elevated, have included fluoranthene, benzo(b)fluoranthene, benzo(k)fluoranthene, benzo(a)pyrene, Benzo(g,h,i)perylene and Indeno(1,2,3-cd)pyrene, this is consistent with many of the PAH

determinands found to exceed the calculated reuse criteria. This suggests that significant leaching of these PAHs into the perched groundwater and subsequently into the receiving surface water reens is currently taking place across the site, and from consideration of the Level 3 Groundwater Excel Worksheets, is likely to continue from re-engineered Made Ground assuming that all of the PAH concentrations determined in shallow groundwaters are dissolved rather than being present in all phases. Where the Level 3 Groundwater Excel Worksheets are modelled to 'apply the degradation rate to all phases', then there is significant attenuation of these PAHs, thereby suggesting that re-engineered Made Ground containing concentrations of these PAHs in excess (up to the maximum determined|) of the soil reuse criteria (**Appendix J**) may be utilised. In reality, it is considered likely (as indicated above) that although attenuation is taking place, and some processes of volatilisation and aerobic oxidation are likely to be experienced, these processes are not significant enough to enable placement of soils with PAH concentrations in excess of the calculated reusage criteria (in 40% and 5% infiltrations scenarios) very close to the surface water reens.

Metals

It may be noted that based upon scenarios where the maximum iron (2390000mg/kg), manganese (408000mg/kg) and vanadium (2880mg/kg) concentrations determined in samples of Made Ground at the site are present, then soils of this concentration and assuming a 5% and more especially a 40% infiltration of surface water following re-engineering and placement of this material show a potential to impact on the quality of a Compliance Point (taken as the nearest reen) located at a distance of approximately 20m away. Where these scenarios have also been modelled using average porewater concentrations (calculated from average soil concentrations for iron, manganese, vanadium), utilising the Equation provided in Table 5.2 of the EA Remedial Targets Methodology Guidance, it is noted that these soils also show, a potential to impact on the quality of a Compliance Point located at a distance of approximately 20m away.

5.4. DQRA Results

The re-use criteria presented in Table 5-4 (**Appendix J**) are compared to maximum and average concentrations of each determinand as recorded from the 1806 (No.) samples of Made Ground..

Earlier Atkins re-use criteria were calculated based upon the assumption that 100% of the rainwater incident upon areas of the site utilised for soft landscaping for both residential and commercial development penetrates into the underlying re-engineered Made Ground. As indicated above, re-use criteria have now been recalculated assuming a 5% and 40% rainwater infiltration into the re-engineering Made Ground. It is considered that these two infiltration values are likely to be more realistic of the redeveloped site following the undertaking of the Made Ground re-engineering works and the incorporation of measures to encourage infiltrating water to move laterally to the reens through a near-surface drainage blanket comprising clean materials.

In comparison with the calculated re-use criteria, the maximum soil sample concentrations continue to exhibit some exceedances (shown as highlighted, cells in Table 5-4 (**Appendix J**)), which are discussed below.

The calculated re-use criteria for the commercial area are greater than for the residential area as a result of the smaller infiltration to runoff ratio.

Inorganics

With reference to the Soil Re-use Criteria presented in Table 5.4, **(Appendix J)** it may be noted that:

Based upon an assumption of a 40% infiltration scenario:

Compared to calculated re-use criteria, exceedances for samples of Made Ground potentially for re-use in a residential scenario were determined for iron, manganese and vanadium, where maximum concentrations of these metals are considered. However, where average concentrations are considered, it may be noted that these values are found to be significantly lower than their respective calculated re-use criteria.

For a commercial re-use scenario, concentration exceedances for iron and manganese were determined. Where average concentrations are considered, it may be noted that all of these values are found to be significantly lower than their respective calculated re-use criteria.

Compared to calculated re-use criteria, significant exceedances were also noted for ammoniacal nitrogen and cyanide for a 40% infiltration in both residential and commercial materials reuse scenarios.

Based upon an assumption of a 5% infiltration scenario:

Compared to calculated re-use criteria, exceedances for samples of Made Ground potentially for re-use in a residential scenario were determined for manganese only, where maximum concentration of this metal are considered. Where average concentrations are considered, it may be noted that the average manganese soil concentration is significantly lower than the calculated re-use criteria for this metal.

For a commercial re-use scenario, with the exception of cyanide, no concentration exceedances were determined.

Compared to calculated re-use criteria, significant exceedances were noted for ammoniacal nitrogen and cyanide for a 5% infiltration in residential and cyanide only in commercial materials reuse scenarios.

Comparison with the more conservative 40% infiltration scenario for ammoniacal nitrogen Cgw for the commercial (510.69.75 mg/l) and residential areas (129.25 mg/l) with the maximum previously reported shallow groundwater concentration (66.1 mg/l) and more recently reported (post 2017) maximum surface water concentration (18.6mg/l) suggests however that these soils represent a low risk to the quality of Controlled Waters in terms of ammoniacal nitrogen contribution. Similarly with 40% infiltration scenario for iron and manganese, the maximum previously reported shallow groundwater concentrations (92 mg/l and 12 mg/l respectively) are lower than the Cgw for the commercial (1702.33mg/land 209.39mg/l) and residential (430.85 mg/l and 52.99 mg/l) areas, again suggesting that these soils represent a low risk to the quality of Controlled Waters. For cyanide, a comparison (40% infiltration scenario) of the maximum previously reported shallow groundwater concentration (1.4 mg/l) with Cgw for the commercial (1.70.64 mg/l) and residential areas (0.43 mg/l) indicates an exceedance. However, average shallow groundwater concentrations (0.13 mg/l) are lower than the Cgw for both commercial and residential areas. The maximum surface water cyanide concentration recorded post-2017 was 0.28mg/l.

Organics

PAHs:

In the case of the highlighted PAH concentrations a selection of which have been further modelled using the EA RT Level 3 Groundwater Worksheets, it may be noted that the levels of exceedance (based upon maximum determined soil concentrations of these specific PAHs, in both 5% and 40% infiltration scenarios), are likely to impact on the quality of water within the Compliance Point (nearest reen), assuming that this reen is at a distance of 20m from Made Ground. However, this modelling does not take account of processes of volatilisation, which may cause some further depletion in the leached PAH concentrations prior to discharge in surface water reens.

Phenols:

Compared to calculated re-use criteria for both 5% and 40% infiltration scenarios, no exceedances for phenols were determined. In addition, the maximum phenol concentration previously reported in shallow groundwater (0.83 mg/l) is compliant with the 5% and more conservative 40% infiltration scenarios Cgw for the commercial (13.10 mg/l) and residential areas (3.32.25 mg/l). As further comparison, a maximum phenol concentration of 0.04mg/l was determined in surface water samples recovered, post 2017.

Petroleum Hydrocarbons based upon an assumption of 40% infiltration scenario:

Exceedances of the re-use criteria are present for several TPH species with respect to the maximum soil concentration within the aromatic C_{10}-C_{21} range for residential reusage and C_{12}-C_{21} range for commercial reusage. However, where average concentrations are considered, it may be noted that these values are all found to be significantly lower than their respective calculated re-use criteria.

Petroleum Hydrocarbons based upon an assumption of 5% infiltration scenario:

No exceedances of the re-use criteria are determined for TPH species under a 5% infiltration scenario.

5.4.1. DQRA Discussion

The previous re-use criteria produced by Atkins and provided in their 2017 CWDQRA Report (Version: 3 and dated February 2017) were purposely presented as conservative values. A principal conservativity was indicated to be the dilution assessment assumption of a simultaneous discharge of the annual volume of surface water runoff and infiltrated water (Section 5.4). It was indicated that in actual fact, the infiltrated water is subject to storage within the Made Ground and travel times are anticipated to be elongated. Applying Darcy's Law (Darcy flux (q) = Ki where K = hydraulic conductivity (m/s) and i = hydraulic gradient (-) (change in groundwater level/travel distance) and using a hydraulic conductivity $1x10^{-7}$ m/s, travel distance of 10 m and hydraulic gradient of 0.013 (assuming 2 m thick Made Ground is fully saturated), the un-retarded travel time within the Western Sub-Area is likely to be 238 years (at a flux of 0.04 m/year). With the current CWDQRA Revision, and additional assessment using EA P20 Level 3 Groundwater RT Worksheet modelling, these parameters have been incorporated and the re-engineered Made Ground has been predicted as presenting a hydraulic conductivity of $1x10^{-7}$ m/s.

The earlier assumption which has been shown to have significant impact on the value of the re-use criteria, has been the degree of infiltration of the incident water into the re-engineered Made Ground. The earlier Atkins assessment assumed that 100% of this water would penetrate into the Made Ground. However, given the proposed hydraulic conductivity ($1x10^{-7}$ m/s) of this re-engineered material, and the introduction of an overlying 6F2 piling mat/drainage blanket (estimated permeability of $1x10^{-3}$ m/s) beneath clean imported topsoils and subsoils, then a significant proportion of this infiltrating water is considered unlikely to penetrate the re-engineered Made Ground. In order to further encourage lateral movement of this incident water toward the nearest reens prior to penetration into the underlying Made Ground, it has been proposed to create a shallow gradient across the surface of the Made Ground within the development plots sloping downwards towards the reens. On this basis, it has been estimated that water infiltration, rates, provided Made Ground re-engineering works are suitably undertaken, may potentially be reduced to 5% penetration.

It was previously indicated in the Atkins 2017 CWDQRA Report that maximum contaminant soil concentrations were present up to two orders of magnitude larger than the commercial area re-use criteria for several TPH and PAH. In view of this, it was proposed that the poorest quality Made Ground material would be relocated to beneath the commercial area, where infiltration is lowest. It was also indicated that where onsite concentrations are greater than the re-use criteria, remediation or disposal of material offsite may be required. The current revision of the re-use criteria has indicated that provided this material is appropriately re-engineered, then a greater proportion of existing Made Ground may potentially be re-used beneath sections of the site proposed for residential redevelopment. The results of additional EA P20 Level 3 Groundwater RT Worksheet modelling, has also suggested that material which contains concentrations of PAHs in excess of the re-use criteria (Table 5.4 (**Appendix J**)), may also (subject to verification) be suitable for placement across most areas of the site provided that a suitably thick buffer zone of uncontaminated materials is placed between the redeveloped plots and the surface water receptors (reens and ponds). Based upon EA P20 Level 3 Groundwater RT Worksheet modelling, it would appear necessary that the width of this buffer zone between this material and existing surface water reens, will need to be in excess of 20m and potentially closer to 200m. The nature of materials utilised in these buffer zones will need further consideration, in order to optimise the potential for biodegradation of organic contaminants, attenuation of dissolved metals and lowering of pH values prior to discharge of these waters into the reens, within which it is proposed to further encourage fauna and flora colonisation.

It was previously considered by Atkins that reported exceedances of the EQS in the onsite surface water samples are a reflection of the current site condition. This is considered to remain an important point with post-development conditions significantly reducing surface water infiltration by reducing the permeability of the Made Ground and increasing the impermeable surface area across the site, causing increased surface water runoff and subsequently, dilution within the reens. Concentrations of ammoniacal nitrogen released from Made Ground are considered likely to deplete over time in surface waters across the site as this component is leached from the residual sources associated with the former coking works. However, there are known to be other potential off-site sources (mainly agriculturally related), which will continue to impact on the quality particularly of the Monks' Ditch. However, surface water reens across the site which are hydraulically isolated from the main river Monk's Ditch but receive inflow from upstream off-site, surface waters

including agricultural land, may also be impacted by atmospheric contribution of ammoniacal nitrogen, again largely from agriculturally related sources.

As indicated above, fluids passing through the weathering BOF (basic oxygen furnace slag) which will be incorporated within the re-engineered Made Ground will potentially provide an ongoing source of dissolved metals and high pH discharge into the surface water reens. However, reducing the permeability of this Made Ground by reengineering, and placement of a greater proportion of impermeable surface cover following redevelopment should reduce contributions from the present (likely) worst case levels.

6. Conclusions and Recommendations

6.1. Conclusions

Rodgers Leask Environmental Ltd (RLE) has been commissioned by St Modwen Developments Ltd (St Modwen) to update and further develop a Controlled Waters Detailed Quantitative Risk Assessment (CWDQRA) of the potential risk to Controlled Waters for the Glan Llyn development at Llanwern, Newport. A Conceptual Site Model (CSM) for the site has been further developed and updated based on the contamination data assessment. Screening analysis of recent soil, soil leachate, groundwater and surface water data (revealed potential moderate to low levels of inorganic and organic contamination present onsite in line with contaminants associated with former steelworks sites (DoE, 1995). Made Ground constituting clayey sandy gravels with local slag, burnt shale, tarmac, concrete, brick and mudstone was found to be a potential source of contamination. Contaminants in the unsaturated zone and shallow groundwater attenuate along the transport pathway, including within the onsite drainage ditches (reens), where groundwater seepage combines with onsite water from the SuDS system before being discharged to the Controlled Waters receptor (Monks' Ditch).

There appears to be no obvious increase or decrease in recorded concentrations of metal determinands within upstream reens and positions downstream within the Kings Wall Reen. However, cyanide concentrations appear to increase downstream within the reen system, possibly as leached contributions are made from deposited wastes associated with the former coking works located within the northern central section of the site. However, there is evidence for decrease again in cyanide concentrations, further downstream, potentially due to complexation with metals such as iron and nickel, particularly in the higher pH (alkaline) conditions which are likely to prevail. There is also noted to be evidence of a possible contribution here from ammoniacal liquors associated with the former coking works, although pervasive slightly elevated concentrations of ammoniacal nitrogen have been recorded in surface waters more widely across the site, and from what appear to be sources upstream of the study site.

It is considered that following the undertaking specific remedial works within the area of the site previously occupied by the coking works, then this should have a positive impact on the reduction of ammoniacal and cyanide leachates which appear to be currently entering the surface water reen drainage system.

Calculation of conservative re-use criteria was undertaken using a dilution assessment methodology based on the site-wide water balance and has now incorporated permeability and infiltration parameters which it is considered are more representative of the redeveloped site. Comparison of re-use criteria against available information regarding the current composition of the Made Ground established that the much of Made Ground is likely to be suitable for re-use onsite, however localised source materials containing high concentration material (particularly elevated concentrations of iron, manganese and vanadium), and ammoniacal and cyanide components, may require remediation, or offsite disposal.

Where materials contain PAH concentrations in excess of the calculated reuse criteria for 40% and 5% infiltrations scenarios are to be used within areas of the site proposed for

residential and commercial reusage, then it concluded that this material should, as a precaution, be placed no closer than 150m-200m from the surface water reens into which infiltrated waters are likely to discharge and materials placed within the 'buffer zone' be engineered to provide a dissolved hydrocarbons and metals (principally iron and manganese), attenuating capability.

6.2. Recommendations

The following recommendations are proposed based on the outcomes of the assessment:

- The current programme of long-term monthly surface water monitoring should be continued at the established current sampling locations to monitor the quality of the reen system during and post-development until it is established that water quality is stable and compliant;
- Discharges into Monks' Ditch from the reens onsite are not to occur until specified quality criteria and quality control systems have been established and are met; and
- The sitewide MMP sets out the overall approach to materials management within the development and is a live document to be updated as the development progresses. In order to appropriately mitigate the risk to Controlled Waters, it is proposed that a remediation strategy be produced in conjunction with updates to the Materials Management Plan (MMP), as required, on a phase by phase basis, to regulate the application of the re-use criteria and establish remediation requirements for any localised source zones.

Appendices

Appendix A: RLEs Reclamation Performance Specification.

Technical Note

Project:	Glan Llyn
Subject:	Reclamation Performance Specification A Turnover - Final
Document Reference:	17480-RLE-18-XX-RP-O-1016
Date:	14/12/2018
Prepared by:	Howel Morris - *Associate* BSc (Hons), MSc, CGeol
Reviewed by:	Neil Fraser - Principal Geotechnical Engineer BSc (Hons) MSc FICE

1. Introduction

Rodgers Leask Environmental Ltd (RLE) has been asked by St. Modwen Developments Ltd to prepare a Reclamation Performance Specification for the turnover to reclaim the reens, 15 acres of the Business Park, the proposed Marshalls factory footprint and thirteen residential phases (3b, 3c, 3d, 4a, 4b, 4c, 4e, 4g, 5a, 5b, 5c, 5d, 5g) of the Glan Llyn development.

This specification is intended to develop reclaimed plots that maintain surface compliant water quality, can satisfy the requirements of the contaminated land planning conditions and provide a stable reengineered platform with an accurate record of retained features to support, as far as practical, a site suitable for the proposed development.

2. Reclamation Strategy

The key points of the strategy for reclaiming the site are listed as follows:

- Pre sample each phase of site,
- Review and update site specific Controlled Waters Risk Assessment criteria,
- Designate areas to receive unsuitable material (both chemically and geotechnically unsuitable) – estimated to be 10% of the volume (eg 200,000m^3 for 2 million m^3 turnover) comprising park & ride plots, business park, sport pitches and noise bunds,
- Designate phases where engineering (small 1m clay bunds to promote protection of primary water routes by increasing residency within plots and reducing contamination loading near to site discharge) is required to further protect surface water,
- Sequence turnover and placement to suit direct placement approach to support chemical and geotechnical compliance,
- Agree proposed placement with Monitoring Engineer
- Turnover of the ground to natural deposits and reengineer the site to a minimum of 5.7mAOD (600mm below the minimum flood level),
- Compact material in accordance with the backfill specification to reduce permeability to limit infiltration and air voids to reduce leachability and conditions for potential expansion of Made Ground containing slag,

- Prepare geotechnical and chemical validation report for each phase.

3. Pre Reclamation Sampling

Prior to the commencement of reclamation works each phase will be trial pitted on a 25m grid sampled in accordance with the following:

- One composite chemical sample every exploratory hole to represent how it will be excavated and placed, (current testing is 1 per metre depth for each trial pit location)
- One composite geotechnical sample every exploratory hole and,
- One composite BRE expansion test (at least one per 2000m3).

The sequencing of the reclamation will need to follow the sampling programme. Pre validated material within stockpiles may require some testing to improve frequency to the required ratio.

The Contractor needs to allow in the programme sufficient time for the receipt and assessment of the contamination results and the slag expansion tests which require a 28-day test but there may be limited capacity. Areas where the Made Ground contains high proportions of slag may be reused in the designated open space or commercial areas rather than reuse within the residential phases.

4. Material Suitability – Chemical

The risk driver for the remediation of site is the controlled waters (water quality within site reens prior to discharge into Monk's Ditch). Therefore compliance with the Environmental Quality Standards (EQS) in the surface waters on site is the primary objective. The soil material placed within the plots will be assessed against the site specific criteria derived within the Controlled Waters Risk Assessment for the site and will use these criteria as guideline for compliance. Initial work will be undertaken to review the CWRA criteria to see if improvements are appropriate based on more recent site specific monitoring data and these will be submitted to the NRW for approval.

It is anticipated that the provision of clean cover will be sufficiently protective of human health providing the retained material complies with CWRA criteria.

In addition to chemical compliance reasonable engineering methods (creation of clay bunds below ground level) shall be employed to lengthen the contaminant travel time and direct the perched water discharge to a suitable point within the surface water system on site. This approach shall aim to use of cleaner material nearer the points of discharge.

Material with exceedances of the CWRA criteria may be retained within the plot if the overall profile of the placed material is assessed to be sufficiently protective of the water quality and human health (with the use of clean cover).

Material not suitable for reuse within the residential phases but suitable for public open space or commercial use shall be reused within commercial plots, park and ride areas, sports pitches and noise bunds.

Material assessed as requiring treatment will be investigated to delineate extent of contamination, excavated for treatment as required to permit reuse within one of the designated areas for lower threshold material. This is likely to apply to areas of gross contamination including but not limited to the coking works and the bitmac plant.

A programme of water quality monitoring shall be undertaken, either an existing agreed monitoring regime and/ or a dynamic monitoring programme to support the reclamation works, for the duration of the reclamation works to assess the developing water quality.

A mechanical method (scrubbing) and/ or natural method (reed beds) of water quality improvement may be deployed as mitigation prior to discharge into Monk's Ditch in the event of non-compliance of the EQS. This action shall be supported by monitored natural improvement in water quality within the reens as the development progresses so that mechanical improvement is a short term measure to mitigate the interim state of a reclaimed site without the rainfall interception of the full redevelopment.

The Contractor's method of working in close proximity of to the reen shall protect the watercourse. This shall also include potential run off from surface water or perched water levels. Chemical testing in accordance with EQS at a frequency approved by Natural Resources Wales. It is anticipated that an approach for monitoring the on site surface waters has been developed by Atkins and agreed with NRW.

The Contractor will manage the perched water as required and will provide compliant test results prior to discharge into the surface water course.

5. Material Suitability – Geotechnical

The following material types or physical properties shall be regarded as suitable for immediate placement with appropriate testing:

- Made Ground containing slag,
- Natural strata
- Crushed concrete
- The above materials, less than 300mm in size

The following material types or physical properties shall be regarded as unsuitable for immediate placement and should be deposited within the one the defined areas for unsuitable material:

- Colliery spoil and / or burnt shale
- Pure slag
- Material with obvious evidence visual & olfactory contamination
- Oversize material

- Scrap metals
- Organic material
- Plastics
- Voided areas
- Alluvium

The material visually regarded as not suitable for immediate reuse within the Site may either be retained until test results confirm the suitability for reuse or moved to one of the designated areas.

6. Formation Embankment Details

Where it is necessary to form an embankment an assessment will be undertaken to assess a minimum factor of stability for the slope. The assessment will take into account available land, characteristics of the material to be used and potential for post construction works to maintain stability. In the absence of detail reen volume/ layout/ profile requirements a minimum slope of 1:2 shall be assumed.

7. Levels

The phases within the site, following turn over to natural geology, will be backfilled with site won material to a minimum level of 5.7mAOD.

8. Turnover & Backfill

Within the boundaries of the site, the property will undergo reclamation to a depth where the natural underlying Tidal Flat Deposits can be confirmed. Known obstructions shall be removed, where they are unsuitable for retention within a normal piling layout, to a depth of 2m below minimum ground level in accordance with the flood mitigation requirements. Material within the site will undergo chemical and geotechnical testing.

Reclamation and subsequent backfill will be undertaken in accordance with the 600 Series (Earthworks) of the Specification for Highway Work (SHW) and each phase-specific Reclamation and Backfill Specification. The location and level of identified obstructions remaining in situ shall be accurately surveyed to the base of excavation and the positions recorded on a drawing.

In situ compaction testing of the placed layers shall be undertaken in compliance with the requirements of the 600 Series (Earthworks) of the Specification for Highway Work (SHW) and results provided to the developer. The backfilled material shall be reengineered to a target of 95% compaction. It will be at the discretion of the monitoring engineer to accept results below 95% to a minimum of 90%. The surface of each compacted layer shall be tested to ensure it meets the requirements of the SHW and a minimum CBR value of 2.5% at the surface.

9. Removal of Obstructions in Site Excavation Area

Shallow foundations and other man made obstructions encountered within the Made Ground and above the level of the underlying natural strata shall be entirely removed. Where isolated structures are encountered below 4.3mAOD that extend into the natural strata and measure less than 2.5m by 2.5m these may be retained on agreement with the engineer to reduce unnecessary excavation and support a nominal 3m grid for future piles. Where other obstructions are encountered which extend below the level of the underlying natural strata (e.g. slag in slag pits) these shall be removed unless otherwise agreed in writing by the Engineer.

Where redundant foundation piles or sheet piles are encountered these shall be cut down to the level of 4.3mAOD, and their location accurately surveyed for a future developer.

10. Grading

Fill material shall satisfy grading requirements for SHW Class 1 or Class 2 material except that a maximum particle size of 300mm shall apply and the maximum particle thickness shall not exceed two thirds of proposed compaction layer thickness.

Oversized material shall be removed, during the process of direct turnover, by visual assessment during excavation of existing ground and during the blade placement, by bulldozer, of the excavated ground prior to compaction. Removed oversize material not viable for crushing may be used in the sports pitches or park and ride areas, stored for an alternative suitable use or processed and tested to confirm material acceptability.

Incidental break up of material during the excavation and reengineering process is acceptable. Under no circumstances shall the crushing, as a specific operation, of slag bearing fill to achieve the required grading be permitted.

11. Reuse of Made Ground Containing Slag

Using the pre testing information the average risk of expansion will be managed as the layers of material are placed. Following the reclamation, surface monitoring points will be installed to monitor and validate stability of the reclaimed plot over a defined period to confirm the plot is within expansion tolerance prior to construction. BRE test results will be used to assess the suitability of material for reuse. A target expansion average for the accumulated material within the plot of 2.5% with a maximum of 5% being adopted. This may be amended based on practical mitigation measures and the proposed criteria will be subject to approval by the NHBC.

Where used as a reengineered material, Made Ground containing slag will be placed at a likely average thickness of 2m. A piled foundation solution with incorporated void (nominally 100mm, beam and block) would mitigate the risk of expansion to the building and the reengineered material is unlikely to cause unstable conditions for roads, services and gardens as the reclaimed plot will comprise weathered, well graded and well mixed layers.

Where there are areas of very slag rich made ground, with a potential for substantial expansion (as measured by the slag expansion results), the Contractor will have to regard this material as suitable for use in a public open space area.

12. Settlement & Stability Monitoring

Existing ground levels, on average, are within 300mm of the minimum ground level for flood requirements, therefore the increase in ground loading is not anticipated to be greater than 1m from the existing ground levels to incorporate an appropriate drainage system. Assuming a piled foundation solution, primary consolidation settlement from an increase in ground levels of 1m is likely to be acceptable for the stability of roads, services and gardens without surcharge given the time between reclamation and final development. An appropriate number of floor level monitoring points will be installed on pads of suitable material (5m x 5m) at the likely finished floor level, approximately 600mm above the reclaimed level, to reasonably replicate the final ground loading.

The floor level monitoring points will be monitored for a period to confirm stability of the site with regard to primary consolidation settlement but will also provide information relating heave stability prior to construction.

13. Land Quality Statement

A Land Quality Statement (LQS) will be prepared by St. Modwen Developments' Environmental Consultant which shall include a factual description of the site and its environs, the geo-environmental works carried out and describe the geo-environmental condition of the site following the completion of the agreed works. The LQS will provide a statement by the Environmental Consultant that planning conditions PC27 and PC28 of outline planning permission 06/0471 have been discharged by Newport City Council prior to final construction for the proposed residential end use. Amendments to existing CWRA criteria, which are relevant to the contaminated land planning conditions, will require approval by the NRW and local authority.

14. Notes for Intended Use

The developers and occupiers of the residential phases and reens, where this specification shall be applied, should consider the following:

- The site is underlain by soft organic rich Tidal Flat Deposits which according to historical information have been in part loaded by the former processes on the site. The site will continue to undergo unavoidable long-term creep settlement; this is normal for such sites.
- The buildings with piled foundations will not undergo creep settlement and therefore maintenance may be required where piled buildings meet ground bearing external areas due to the potential for differential settlement. Consideration should be given to boundary fences rather than brick walls. Extensions/ conservatories will require separate assessment to ensure settlement is considered prior to design of foundations.

- The storm water drainage of shall be constructed appropriately so that it does not leak into the underlying Made Ground. Poorly constructed drainage with headwalls into surface water features have the potential to generate leachate through infiltration into the Made Ground and then provide a pathway directly into the surface water.
- The external areas (roads, pavements, open space) have not been designed for the prolonged parking of HGVs, storage of materials, new buildings etc as these activities have the potential to cause settlement.
- The external areas may require maintenance due to creep settlement in the underlying Tidal Deposits.
- Flexible connections should be considered for services entering the piled buildings.
- Dewatering may result in localised reduction in groundwater level, which would induce localised consolidation settlement.

Introduction

The Made Ground within the Glan Llyn site is generally compliant with residential, open space and commercial human health soil screening criteria. It is recognised that human health criteria is not intended to protect controlled waters but this note has been prepared to support the re-engineering of the onsite Made Ground material as a remediation measure in order to support parameters adopted within the Controlled Water Risk Assessment (Ref.1 5111373-OUT-RPT-0275). This is to be achieved by reducing the permeability of the shallow Made Ground soils by excavation and re-compaction, and providing a fall across its upper surface; as well as the placement of an overlying granular material to create a preferential pathway to minimise the potential for infiltration of precipitation into the underlying re-engineered Made Ground. The reduction in the permeability of the re-engineered Made Ground will attenuate the flow of precipitation through the Made Ground. This will have the intended benefit of increasing the volume intercepted rainwater against water infiltrating through the Made Ground within the surface water drainage system. Thus improving the surface water quality within the reens at the perimeters of the development plots.

It is worth noting that the re-use criteria developed within the CWRA report are protective of the surface water quality in the event that the full annual amount of water infiltrated and intercepted by the site be discharged to the reen system instantaneously. This technical note has been prepared to record the rationale of the chosen values for the permeability parameters used within the Controlled Waters Risk Assessment.

Site Permeability

The interception rates (where precipitation is intercepted by various development surfaces and flows into the surface water drainage system) and infiltration rates (where precipitation infiltrates through permeable gardens or landscaped areas into the underlying material) have been based on the figures provided in the drainage strategy prepared by Rodgers Leask (Rodgers Leask, 2016. Site Wide Surface Water Drainage Strategy Addendum for St Modwen Ltd. Rev 4 D12/084). The report provides figures for impermeable areas within the residential land and when this is compared with the total residential area a ratio of 60:40 is produced in favour of interception. The residential area includes all ancillary land including roads, landscaping features, drainage features, gardens and parks. The commercial area produces a ratio of 90:10 in favour of interception. The ratio provided within the drainage strategy does not account for the permeability of the percentage listed as permeable.

The respective adopted permeable values of 40% and 10% assume free draining material where the precipitation may freely percolate through the underlying materials. However, there are a number of factors resulting from the re-engineering of the development plots that significantly reduce the potential for infiltration of precipitation into the underlying Made Ground. The specification for the re-engineering of the Made Ground (Ref.2 5111373-LLA-OUT-225 Guidance for the Reuse of Made Ground Containing Slag, Dec 2016) requires compaction to a minimum 95% of maximum dry density and a minimum 5% CBR at finished levels to be achieved. The re-engineering of the plots into a stable platform with a fall from the centre to the periphery, and the materials used, will produce a preferential pathway. Based on soakaway tests carried out in the re-engineered Made Ground, and the results of Particle Size Distribution (PSD) laboratory tests carried out on the material, the site won re-engineered Made Ground within the plots is assessed as having a permeability of approximately 1 x 10^{-7} m/s (i.e. poor permeability). The properties of the re-engineered Made Ground are shown in Table 1 below.

Table 1: Properties of the Re-engineered Made Ground

Made Ground	PSD No./ Average	BRE Soakaway Test Result	Adopted Permeability(k)
Test 1	102 No./ 11% fines, 22% sand, 62% gravel, 5% cobbles	Fell 4mm in 3hrs	1 x 10^{-7} m/s
Test 2		Fell 20mm in 2hrs	1 x 10^{-7} m/s

* Unable to calculate an infiltration rate as the amount of infiltration was minimal during the test period indicating low permeability.

The PSD test samples were taken from existing stockpiles of site-won material. The soakaway tests were carried out on a re-engineered development plot within the site using typical stockpiled site-won Made Ground. The permeability of the re-engineered Made Ground was based on the values included within Soil Mechanics Principles & Practice, 3rd Edition, Table 3.3 (Ref.3) for a material with poor drainage characteristics.

The overlying gravel layer to be placed above the re-engineered Made Ground is expected to have a permeability of 1 x10^{-3} m/s (good) based on the values for a material on the boundary between a clean gravel and a clean sand provided in Soil Mechanics Principles & Practice, 3rd Edition, Table 3.3 (Ref.3).

The permeability will be validated on a plot by plot basis by undertaking soakaway tests. The designed fall at the top of the re-engineered Made Ground will promote flow within the more permeable granular layer and the infiltrated water will seek the course of least resistance, potentially flowing within the layer until it daylights at the reens at the periphery of the plot.

Landscaping/ Drainage & Public Open Space

The green areas of the site (including landscaped areas, parks & gardens) have been included within the permeable ratio for the residential areas. The green areas will have a minimum subsoil thickness of 450mm and in this region of south Wales red marl is a readily available subsoil which has already been used in some areas of the Glan Llyn development and which has a low permeability. The reduced permeability of areas assumed to allow free downward migration of rain water will further reduce the volume of rainwater able to infiltrate the re-engineered Made Ground. It is considered that a placed / un-compacted marl will have a permeability of 1 x 10^{-8} m/s, consistent with a stratified clay material (Ref.3). The reduced permeability of the green areas will also help improve the water quality within the drainage system.

Conclusion

The reduction in the permeability of the re-engineered Made Ground is intended to further improve surface water quality by attenuating the flow of infiltrated precipitation through the material. The reduced permeability of the Made Ground dramatically increases the transport time of the rainwater through the material, in contrast, a large volume of intercepted rainwater is able to reach the surface water reen system rapidly via the storm water drainage system. Therefore it is anticipated that the composition of surface waters will be dominated by intercepted clean rainwater. In reality, the large volume of intercepted precipitation and contrasting low volume of infiltrated seepage entering the reens annually will contribute to further improving water quality in a system already designed to maintain a compliant water quality within the surface water reens of the development.

Appendix D: Glan Llyn Diagrammatic CSM

Area covered by landscaping = 23.8%

40% Infiltration into made ground

5% Infiltration
Increased distance from surface water

GENERAL NOTES

NO DIMENSIONS TO BE SCALED OFF THIS DRAWING.

THIS DRAWING TO BE READ IN CONJUNCTION WITH ALL RELEVANT ARCHITECT'S AND ENGINEER'S DRAWINGS.

ALL DIMENSIONS ARE IN MILLIMETRES UNLESS NOTED OTHERWISE.

ALL LEVELS ARE IN METRES UNLESS NOTED OTHERWISE.

ANY DISCREPANCIES NOTED ON SITE ARE TO BE REPORTED TO THE ENGINEER IMMEDIATELY.
